INTRODUCTION

Musculoskeletal and neurological disorders include a wide spectrum of diseases with different related symptoms in terms of entity, duration, prognosis that negatively influence life quality of patients. Different therapeutic approaches are available, such as pharmacological treatments, dietary supplementation, surgery, manual and electro - medical physiotherapy. A new non-invasive strategy for the treatment of these pathologies, especially in the early stages of the...
This retrospective observational study investigates the effects of an infrared –trapping and focusing plaster ([FIT-PATCH], D.FENSTEc s.r.l. Altvilla Vicentina (VI) ITALY) in a clinical setting of different musculoskeletal and neurological symptoms.

**MATERIALS AND METHODS**

**Patients**

We reviewed medical records (electronic or paper-based) of 100 patients that had appealed to our “Second Opinion Medical Consulting Network”, Medical Centre (Modena, Italy), between September 2017 and March 2018, because of musculoskeletal and neurological disorders. Patients were aged over 29 years and were affected at least 6 months by different musculoskeletal (n = 50 patients) and neurological disorders (n = 50 patients) predominantly in the neuro – musculoskeletal vegetative background with an attested related symptomatology (local pain) and diagnosis. The Second Opinion Medical Network is a consultation referral web and Medical Office System recruiting a wide panel of real-time available specialists, to whom any patient affected by any disease or syndrome and not satisfied with the diagnosis or therapy, can apply for an individual clinical audit6. Due to the doctor-patient communication gap, most of the patients usually wander around the medical websites looking for proper answers to their health problems. However, this search often becomes compulsive and obsessive and is frequently ambiguous and frustrating. Palmieri et al., describe this borderline or even pathological behaviour as the “Web Babel Syndrome” – a psychological imbalance affecting young and elderly patients, especially those with multiple synchronous diseases who receive from their caregivers heterogeneous and misleading information or advice, including confused, contradictory statements and prescriptions8. To deal with this problem, the Second Opinion Network aims to be a useful “problem-solving” support revisiting each diagnostic and therapeutic step and properly re-addressing tailored treatments and prognoses, as well as preventing unnecessary investigational procedures and unhelpful and expensive medical and surgical interventions6.

All patients used pharmacological treatments, dietary supplementation, surgery, manual and electro - medical physiotherapy especially for the management of pain and stiffness drawing partial benefit from them. The most used drugs included analgesics, non-steroidal anti-inflammatory drugs (NSAIDs), simple, and combination opioid analgesics, barbiturates, lidocaine, corticosteroids, hyaluronic acid, muscle relaxing drugs and vitamin B12 at high doses. However, their use is very often related to light, moderate and severe side effects (e.g. hypersensitivity reactions, sensation of pressure or constriction, flushing to face and in the thoracic region, asthenia, myalgia, drowsiness, insomnia, restlessness, vertigo, gastrointestinal symptoms, skin rashes, nausea, vomiting, etc.), as well as being limited by frequent drug interactions and contraindications. Dietary supplementation included herbal products and nutraceutical supplemenations, while electro-medical physiotherapy was conducted by laser therapy, iontophoresis, magneto therapy, electrostimulation, etc.

In our clinical practice, we suspended (wash out) previous treatments for a period of 2 weeks, and then the FIT therapy was administered.

The selected patients were informed, via individual interview, and informed consent previously approved by the Local Institutional Review Board under the Helsinki Declaration.

**Study design**

We conducted a retrospective observational study for 1-month duration. During this period, patients were...
educated to apply a FIT therapy patch every 5 days and then to replace the patch with another one until the end of the study period (Photos 1-6).

Different typologies of FIT therapy patches were available according to the anatomical area to be treated and every patient used the most appropriate patch according to the clinical examination by the medical doctor. The available formats were “universal”, “cervical”, “shoulder”, “elbow”, “lumbar”, “knee” and “ankle”. All the patches were water-resistant, so it was possible to have shower wearing it.

Photo 1: A 50 years old male patient with intense pain on inferior forearm

Photo 2: A 29 years old female patient with neck pain

Photo 3: A 35 years old male patient with cervical pain

Photo 4: A 70 years old male patient with foot pain

Photo 5: A 45 years old female patient with intense pain on shoulder

Photo 6: A 37 years old male patient with local elbow pain
The first clinical examination consisted in the evaluation of the physical status of the patient. Tolerability and adverse effects were assessed weekly during the treatment period through direct contact (email or telephone) with the patients or their parents.

Quality of life (QOL) assessment was performed using the Short Form-36 (SF-36) health survey questionnaire before starting the treatment and after the fourth week. The questionnaire measures health-related quality of life in eight domains: physical functioning (A), role limitations due to physical health (B), pain (C), general health (D), energy/fatigue (E), social functioning (F), role limitations due to emotional problems (G) and emotional well-being (H). The percentage scores range from 0% (lowest or worst response) to 100% (highest or best possible response).

Visual Analogue Scale (VAS) was adopted for pain assessment before starting the treatment and after the fourth week (0–100 mm; 0 mm = minimum pain; 100 mm = maximum pain).

**Statistical analysis**

The statistical analysis was performed using the Mann-Whitney test (continuous variables not normally distributed) and the chi-squared test (categorical variables). A commonly used measure of linear correlation, the Pearson correlation coefficient, denoted by r, was reported. Statistical significance was set at a P value < 0.05, and all data and graphics were analysed using the R software, version 3.1.2.

**RESULTS**

**Patients.** 100 patients [50 women and 50 men, aged between 29 and 86 years old (mean age 59 years old)] followed the treatment for 3 months. 20 women (40%) were affected by neurological disorders and 30 (60%) by musculoskeletal disorders, while 30 men (60%) were affected by neurological disorders and 20 men (40%) by musculoskeletal disorders.

Most frequently, the locally treated anatomic area included the cervical – lumbosacral spine tract, the coxofemoral, the femoro-tibial, the acromio-clavicular joints and arms, due to symptomatic epicondylitis, coxo-arthrosis, arthritis, and hernias. Figure 1 shows medicated body areas and number of affected patients.

SF-36 revealed a significant improvement in the physical component scores (A-B; P < 0.03), pain score (C; P < 0.02), general health score (D; P < 0.03) and in the emotional component scores (G-H; P < 0.03) after treatment (Figures 2-5 and Figures 8-9). No significant differences in energy/fatigue (E) and social functioning (F) scores were found.
after the fourth week of treatment (P > 0.05) (Figures 6-7). A significant improvement in VAS pain score was also found (P < 0.02) after treatment (Figure 10). A perception of heat was reported in about 20% of patients, and was considered beneficial in order to resolve the symptoms. The treatment with FIT therapy patches was well tolerated by all the patients. Any adverse effects have occurred.

**DISCUSSION**

This retrospective observational study evidences that the treatment of patients with neurologic and musculoskeletal disorders with FIT therapy patches improved pain, physical and emotional status and related role limitations by alleviating the symptomatology. Neither adverse events nor skin intolerance to the patch were detected along the trial.

Although a light perception of heat that has been reported in about 20% of patients, we believe that the antalgic action is not heat-dependent. It remains to be defined that the invoked mechanism of action is not due to the simple occlusive mechanism of the patch, which prevents the transpiration sebaceous/sweat increases the local temperature, generating a gradient that has therapeutic effects.
As to the infrared putative therapeutic role, there have been a number of studies on various biological effects caused by THz waves. The majority of them deal with thermal and non-thermal effects due to THz irradiation\textsuperscript{10,11}. For example, the influence of a high peak electric field of the THz wave has been investigated showing DNA remodelling effects\textsuperscript{12}. Besides these studies, Feldman et al. have reported that the human sweat ducts in skin play a significant role in the interaction of THz wave with the skin\textsuperscript{13}. In fact, it has been experimentally defined that the sweat duct can act as a low-Q-factor helical antenna when the helically-shaped sweat ducts are filled with the highly electrolytes concentrated conductive sweat fluid. The conductivity mechanism in this case is assigned to proton hopping though ordered aqueous H-bond networks, rather than ionic conductivity. These results have also been assessed by Yang et al\textsuperscript{14}. Based upon the numerical modelling and experimental data, it was suggested that the sweat duct play a role in characterizing the phenomena of resonance behaviour. Similarly, Shaferstein et al. reported that the sweat ducts play a significant role in millimetre wave absorption, indicating possible thermal effects induced by such waves\textsuperscript{15}. Recently, it has been investigated the absorbance of sub-THz radiation by human skin and demonstrated that the absorption of THz wave is governed by the topology for the skin and the sweat duct\textsuperscript{1}. The helically structured sweat ducts play thus a significant role in the interaction with THz and the updated research trends on this issue have been addressed to channel characterization in human skin for body-centric nano-communication\textsuperscript{1} and the development of extremely high-power gyrotron operating in sub-terahertz frequency region and high data-rate terahertz communication links\textsuperscript{1}.

Experimental studies conducted by the CNR Nano of Pisa compared emissivity of a patch covered by a powder of titanium metal dioxides and control titanium metal dioxides – free patch at the wavelength of 10.8 µm and 37° temperature in order to investigate if the addiction of titanium to the patch influences the patch-emitted energy. Results showed a greater value of emissivity (+5%) with the titanium-covered patch compared to the control patch, and a 100% emissivity between 7 and 11 µm wavelength, suggesting a strongest capacity to irradiate energy played by the titanium metal dioxides compared to a black body that was responsible to the therapeutic mechanism of action (personal communications). Since also our biological body structures naturally emit FIW probably, the addiction of titanium might contribute to the spread of the body energy and to modulate the physiological functions. However, we do not know if patch thickness might influence therapeutic response.

On this basis, the relationship between sweat glands density and the fit patches effects on the skin, and it’s nociceptive receptors should be deeply investigated.

Apparently, the subcutaneous muscle mass does not seem to definitely interfere with the therapeutic response.

Actually quite often, the FIT PATCH mediated pain improvement reduced the NSAIDs or steroids administration schedule and it was not effective in cases of nerve mechanical compression (such as in herniated cervical or lumbar disks, articular conflicts nerve trapping like in the tennis elbow; etc.).

**CONCLUSIONS**

FIT therapy patches improved the symptoms probably interacting with the skin sweat glands whose ducts supposedly act as a low-Q-factor helical antenna THz irradiation amplifying the infrared signals emitted by the fit plasters. Completely marginal and irrelevant for therapeutic purposes, the hypothesised synergistic effect of the occlusive mechanism due to the adhesion on the surface of the skin, which inhibits the sweat sebaceous perspiration, increases the local thermal gradient; in fact, the heating induced by the occlusion is subjectively variable and acts strictly at the site of application, while the symptomatic effects of the application of FIT are also expressed remotely. The intrinsic chemical properties of the FIT patch are therefore characterized to absorb and concentrate infrared waves, generate endogenously, reverberating them in the affected district and accelerating functional recovery by dissipating cell and neurochemically-mediated inflammation.

**ACKNOWLEDGEMENTS**

We greatly acknowledge D.FENSTEC s.r.L., Altavilla Vicentina (VI), ITALY, for providing us FIT-PATCH.
