An antioxidant activity of Cinnamomum tamala improves histopathological alterations and biochemical parameters in alloxan induced diabetic rats

Mamta Pochhi

Associate Professor, Department of Biochemistry, Shri Shankaracharya Institute of Medical Science, Bhilai, India

ABSTRACT

Background: Diabetic mellitus is a multifactorial disorder associated with its devastating consequences has assumed epidemic proportion. Diabetes mellitus (DM) is a global health problem and the incidence of DM is increasing at alarming rate all over the world. Many Indian medicinal plants have been reported to possess potential anti-diabetic activity and could play important role in the management of diabetes with less adverse effects.

Aims and Objectives: The main objective of this study was to focus on the anti-diabetic activity of Cinnamomum tamala, with special reference to its curative and protective role in alloxan induced diabetic rats. Attempts were further made to study the antioxidant properties of C. tamala leaves.

Materials and Methods: The diabetic rats were administered orally with the aqueous leaves extracts of Cinnamomum tamala (250 mg/kg) for 30 days. The results were compared with standard drug Tolbutamide.

Result: The alloxan treated diabetic control rats showed a significant increase in the plasma glucose, glycosylated hemoglobin (HbA1c), glucose-6-phosphatase, aldolase, LDH, ALT, AST, ALP and GGT activity, free radicals formation with a concomitant decrease in glycogen content in the liver and serum insulin level and phosphoglucoisomerase and hexokinase activity in tissues as compared to normal control rats. Oral administration of C. tamala extract for 30 days showed significant result as compared to Tolbutamide and diabetic control rats.

Conclusion: On the basis of above findings it can be concluded that extracts of C. tamala to alloxan induced diabetic rats showed significant positive changes in the biochemical and histopathological parameters related to carbohydrate and protein metabolism. Further studies should be undertaken to find out the molecular mechanism of C. Tamala.

Key words: Cinnamomum tamala; Blood glucose; Insulin; Glycogen; Glycosylated hemoglobin; Marker enzymes; Antioxidants; Histopahological findings

INTRODUCTION

Diabetes mellitus (DM) is a chronic endocrine disorder, involving metabolic disorders of carbohydrate, proteins, and fats resulting from inadequate pancreatic insulin secretion with or without concurrent impairment of insulin action. According to the American diabetes association, the chronic hypergylcaemia is associated with long-term damage, dysfunction, and failure of different organs, especially the eyes, kidneys, nerves, heart and blood vessels. Previous studies have demonstrated that DM exhibits enhanced oxidative stress and highly reactive oxygen species (ROS) production in pancreatic islets due to persistent and chronic hyperglycemia, there by depletes the activity of the antioxidative defense system, and thus promotes free radical generation. Oxygen free radicals have been suggested to be a contributory factor in complications of DM and the antioxidants may be useful in preventing it. Therefore supplementation of therapeutics with antioxidants may have a chemoprotective role in diabetes.
Many Indian medicinal plants have been found to be useful because of rich source of various bioactive phytochemicals in the management of diabetes. Medicinal plants provide better alternatives as they are less toxic, easily available and affordable and many of them are currently available drugs have been derived directly or indirectly from them.\textsuperscript{7,8}

C. tamala is belonging to the Lauraceae family. The leaves, known as tejpat, tejpatta, or tejpata in Hindi, tamalpatra in Marathi, and Indian Cassia in English which is widely used in pharmaceutical preparations because of its hypoglycemic, stimulant and carminative properties.\textsuperscript{9} Leaves of this plant are effective in diabetic rats have antioxidants as well as have hypoglycemic anti-inflammatory and immunomodulation properties\textsuperscript{10} and the bark was reported to have anti-diabetic activity by using α-amylase inhibition assay.\textsuperscript{11,12}

Only scarce data is available on effect of C. tamala on other parameters. Our aim was to explore the antioxidant activity of C. tamala improves histopathological alterations and Biochemical parameters in alloxan induced diabetic rats and compare the effect with standard drug Tolbutamide.

The Indian medicinal plant Cinnamomum tamala Nees and Eberm or Indian bay leaf is an evergreen, medium-sized tree belonging to the family Lauraceae. The leaves, known as tejpat, tejpatta, or tejpata in Hindi, tamalpatra in Marathi, and Indian Cassia in English, are usually olive green in colour, may have some brownish spots and have three veins running down the length of the leaf. The leaves of this tree have medicinal properties and are reported to be used in treatment of numerous ailments. The produce of the plant is also used as food, fodder, medicine and timber in Uttarakhand state as well as in other Himalayan regions of India.\textsuperscript{1} Various kinds of leaf extracts of C. tamala have previously been reported to have anti-inflammatory,\textsuperscript{5} antioxidant,\textsuperscript{6} antiulcer,\textsuperscript{7} anticarcinogenic,\textsuperscript{8} antidiarrhoeal\textsuperscript{9} and antidiabetic.\textsuperscript{10}

### Preparation of plant extract

The leaves of C. tamala were collected locally. Plants were confirmed by Taxonomist.

For preparation of aqueous C. tamala, leaves were properly clean and powdered in an electrical grinder and stored at room temperature. About 20 g of dry leaf powder was mixed in 100 ml of distilled water at 100°C for the preparation of aqueous hot extracts. The flasks were kept overnight. Supernatant was filtered with muslin cloth and filtered twice with Whatman No. 1 filter paper. The supernatant collected was dried to form gel. Water extract were lyophilized and stored at 4°C until used.

### Doses

250 mg/kg body wt/day of powder of C. tamala dissolved in 5ml of D. water given to experimental rats orally.

### Selection of animals

Male albino rats weighing 100-150 grams were used for the experiments in the present study. The animals were fed with standard laboratory diet and allowed to drink water ad libitum under well ventilated conditions of 12 h light/dark cycles in the animal room of Government medical college, Nagpur during the experimental period.

### Induction of diabetes

Group I rats were injected with distilled water as a normal control. Overnight fasted rats in groups II, III, IV and V were administrated a single intraperitoneal injection of a freshly prepared aqueous solution of alloxan at a dose of 18 mg/kg/wt. The animals were considered as diabetic, if their blood glucose values were above 200 mg/dl on the 3rd d after alloxan injection. The treatment was started on the 3rd day after confirmation of diabetic condition with C tamala (250 mg/kg/wt) and Tolbutamide (300 mg/kg/wt) in 10 % ethanol solution to group IV and V respectively, which was considered as the 1st d of treatment. The treatment was continued for 30 days.

At the end of experimental period, the animals were deprived of food overnight and sacrificed by decapitation at the end of respective experimental periods. The whole blood and serum collected was used for biochemical estimations. The liver was excised immediately and thoroughly washed with ice-cold physiological saline and stored at −20°C until further used.

### Analytical methods

Autoenzyme kits were obtained from 6Ranbaxy and Accurex Biomedical PVT LTD. diagnostic company.

Plasma glucose\textsuperscript{13}, glycosylated hemoglobin\textsuperscript{14}, Insulin\textsuperscript{15}, liver glycogen\textsuperscript{16}, Hexokinase\textsuperscript{17}, Pglucoisomerase\textsuperscript{18}, Aldolase\textsuperscript{19}, LDH\textsuperscript{20},Glucose-6- phosphatase\textsuperscript{21}, AST, ALT\textsuperscript{22}, ALP\textsuperscript{23}, GGT, GSH level\textsuperscript{24} and SOD\textsuperscript{25}

### Histopathological investigation

Liver tissues for histopathological analysis were fixed in 10% formalin solution. After fixation, tissues were embedded in paraffin; solid sections were cut at 4μm and stained with haematoxylin and eosin.\textsuperscript{26} The sections were examined under light microscope, and photomicrographs were taken.

### Statistical analysis

All the data were statistically evaluated and the significance calculated by using student’s test. All the results were expressed as mean ± SEM.
RESULT

The result revealed in Table 1, that after 30 days treatment, it was observed that the animals treated with C.tamala extract (250mg/kg) and Tolbutamide showed significant decrease in glucose (P < 0.01), glycosylated hemoglobin (P < 0.01) in experimental diabetic rats. There was also increased in glycogen content of liver (P < 0.05) with significant increased in Insulin level (P < 0.01) with C. tamala or tolbutamide treatment as compared to diabetic control.

Table 2 shows the significant improvement in the activity of Glucose metabolizing enzymes (Hexokinase, aldolase, LDH, P-gluco isomerase and Glucose-6-phosphatase).

Table 3 the data shows the decreased in liver enzymes (AST, ALT, ALP and GGT).

Table 4 reveals a significant decrease in antioxidant enzyme activities SOD and antioxidant GSH were observed in the hepatic tissues in diabetic control group when compared with normal control group. But after treatment with C. tamala extract in diabetic rats shows significant raised in SOD and GSH level as compared with DC group.

Microscopic examination

The effects of C. tamala on histopathology of liver in alloxan induced diabetic rats are shown in Figures 1-4.

DISCUSSION

Diabetes mellitus is currently a major public health concern, because its incidence and prevalence are elevated and increasing, reaching epidemic proportions. Cumulative evidence has shown that poorly and erratically controlled hyperglycemia produces abnormally high levels of ROS, and these reactive substances could react with essential molecules such as lipids, proteins and DNA, leading to histological changes as well as functional alterations.

Diversity of medicinal plants and spices containing various phytochemicals with biological activity serve as viable source of drugs for the world population. Several phenolics, flavonoids and alkaloids possess marked antidiabetic activities. In a previous study, terpenoids and flavonoids have been reported to increase the concentration of antioxidants. Rupasinghe et al. have reported that saponins possessed hypocholesterolemic and antidiabetic properties. The presence of these phytochemicals supports the claim for the medicinal uses of C. tamala as potent antioxidant and hypoglycaemic agent.

After alloxan injection the rats showed higher glucose level and lower level of insulin when compared to normal control rats. From the results of the present study, it was observed that treatment with C. tamala extract decreased the serum glucose and increased serum insulin in diabetic rats. The possible mechanism for lowering of glucose level might be due to stimulation of insulin secretion from remnant pancreatic β-cells, either by promoting glucose uptake and metabolism, or by inhibiting hepatic gluconeogenesis. This is confirmed by histopathological observations which show that the structural integrity of islets of Langerhans was restored towards normalization.

The study showed that significant decreased the content of liver glycogen in diabetic rats. But after administration of herbal extract shows increased the glycogen content.

in rat liver to near normal. This might be because of enhanced rate of glycogenesis or inhibited glucogenolysis due to stimulation of insulin release resulting in improved mobilization of blood glucose towards liver glycogen reserve or storage.\textsuperscript{34,35}

As per previous data reported by Udayakumar et al.\textsuperscript{36} Glycosylated haemoglobin is produced progressively and irreversibly through glycosylation of haemoglobin over a period of time and subsequent browning reaction is enhanced by increased glucose levels, and this glycation itself further induces the formation of oxygen-derived free radicals. It is stable till the life of the RBC and is unaffected by diet, insulin or exercise. Therefore, it is an excellent marker of overall glycemic control. A significant decrease in HbA1c observed with C. tamala treated rats, which could be due to the result of improved glycemic control by the extracts.

Glucose consumption (glycolysis) and production (gluconeogenesis) are the important process for maintaining the normal sugar, take place in the liver where several enzymes are involved. Insulin regulates carbohydrate metabolism via controlling the activities of numerous metabolic enzymes in the liver by modifying the uptake and consumption of glucose in target organs such as kidneys, skeletal muscles, and adipose tissues.\textsuperscript{37} In our study, it was found that the activity of hexokinase decreased in diabetic rats. Insulin deficiency is the characteristic of diabetes that leads to the impairment in the activity of this enzyme. But after treatment with C. tamala increased the activity of this enzyme due to which glycolysis can be activated and the use of glucose may increase. These results support the earliest finding of phytochemicals and medicinal plants.\textsuperscript{38-40} Hence the finding suggests that extract was improving the glucose metabolism by increasing the utilization of glucose.

Decrease in activity of phosphoglucoisomerase might be expected to inhibit the proportion of glucose 6-phosphate metabolized via the glycolytic pathway.\textsuperscript{41}

Aldolase, another key enzyme in the glycolytic pathway, increases in diabetes and this may be due to cell impairment and necrosis.\textsuperscript{42} In experimental diabetes the cells are subjected to alloxan induced-damage and very often exhibit glycolysis after a period of increased oxygen uptake.

Glucose-6-phosphatase is the key enzyme of gluconeogenic enzymes because it regulates both glycogenolysis and gluconeogenesis process.\textsuperscript{43,44} The activity of glucose 6 phosphatase in diabetic rats was increased in the liver as compared to normal rats, probably due to insulin insufficiency because under normal conditions insulin acts to suppress gluconeogenic enzymes. After treatment with C. tamala inhibited the glucose 6 phosphatase enzyme activity as reported in other studies on phytochemicals\textsuperscript{45}, probably resulting in the restoration of blood glucose and glycogen content in the liver. This effect may be due to the presence of tannin, saponin, flavonoids and other constituents presence in the extract which could act synergistically or independently in enhancing the activity of glycolytic and gluconeogenic enzymes.

Lactate dehydrogenase (LDH) is the enzyme that helps to catalyze the interconversion of pyruvate to lactate and vice-versa in the glycolysis process.\textsuperscript{46} Increased level of LDH activity in diabetic rats is linked with less insulin availability in diabetes. However, treatment with extract decreases the activity of LDH may be because this extract controls the amount of pyruvate and NADH, thus it helps to process oxidation of glucose in mitochondria. Similar findings were reported by others.\textsuperscript{47,48}

Elevated levels of AST, ALT, ALP and GGT are indicative of cellular leakage and loss of functional integrity of the hepatic cell membranes implying hepatocellular damage.\textsuperscript{49} In the present study, after alloxan injection induces hepatocellular damage, which is one of the characteristic changes in diabetes as evidenced by high serum levels of AST, ALT, ALP and GGT in diabetes, suggesting possible damage to the liver. But after treatment with C. tamala showed a significant reduction in the levels of these enzymes when compared to the diabetic untreated control. Therefore it confirm that C. tamala has some hepatoprotective potentials in diabetic rats, thereby showing its non-toxic nature.

The free radicals and reactive oxygen species are might be playing an important role in causation and complications in diabetes mellitus.\textsuperscript{50} Vital tissues are capable for antioxidant defense mechanisms, which include the concerted action of both antioxidant enzymes and nonenzymatic antioxidants. Activities of altered antioxidant enzymes SOD and glutathione metabolism results in an imbalance of oxidant/antioxidant defense systems leading to the accumulation of highly reactive oxygen free radicals.\textsuperscript{51} In the present study, we observed a decrease in antioxidant enzymes markers in liver tissues of diabetic rats in addition to increased blood glucose with decreased plasma insulin levels. The alloxan induced diabetes is associated with the generation of ROS, which causes oxidative damage.\textsuperscript{52} When these diabetic rats treated with C. tamala extract showed the proper functioning of hepatic tissues. Thus the extract of C. tamala might protect the liver tissues against the cytotoxic action of alloxan.

Histopathological examination of liver of diabetic rats revealed morphological changes. The effect of C. tamala
on the histopathological changes of diabetic liver is promising.

**CONCLUSION**

In conclusion, our findings showed that C. tamala markedly reduced hyperglycemia and associated oxidative complications (increased antioxidants markers including enzymatic and nonenzymatic antioxidants) in alloxan induced diabetic rats. Thus, the present study has shown that the phytochemicals as total phenolics, total flavonoids present in C. tamala has protect the liver against alloxan induced diabetic rats due to decreasing the levels of oxidative markers and improvement of antioxidants systems and normalized the histopathological changes.

Experimental evidence obtained from this study is encouraging enough to warrant further studies on the C. Tamala leaves extract to find out its mechanism of action for treatment of diabetic complications.
