Pretoria, South Africa

Peer reviewed

### Abstract

Human immunodeficiency virus (HIV) remains a significant public health challenge globally. While antiretroviral therapy (ARVs) and pre-exposure prophylaxis (PrEP) are proven interventions for prevention and treatment, their integration is hindered by barriers such as poor adherence, stigma, economic constraints, and limited healthcare infrastructure. This study aimed to explore the challenges and opportunities associated with integrating ARVs and PrEP into HIV prevention strategies. This narrative literature review synthesised evidence from multiple peer-reviewed studies addressing adherence challenges, stigma, healthcare access, and the economic implications of ARVs and PrEP. Data sources included global and regional research focused on low and middle-income settings. Findings revealed that adherence remains a critical concern, influenced by side effects, pill burden, stigma, and psychosocial factors. Economic barriers and limited healthcare access reduce uptake, particularly in resource-limited contexts.

Nevertheless, evidence suggests that integrating ARVs and PrEP could significantly reduce HIV transmission rates and healthcare costs. Public awareness and targeted education are essential in overcoming stigma and improving adherence. Strengthening the integration of ARVs and PrEP into HIV prevention requires community-based education, enhanced healthcare infrastructure, and innovative financing mechanisms. Policy interventions should prioritise stigma reduction and support for adherence. Future research should focus on long-term adherence strategies, cost-effective distribution models, and mitigating drug resistance to maximise the effectiveness of ARVs and PrEP in combating HIV/AIDS.

## Introduction

Globally, HIV/AIDS has remained a major global health issue and continues to represent a significant health burden worldwide, with millions of new infections reported each year. Combining antiretroviral therapy (ARVs) and pre-exposure prophylaxis (PrEP) offers a dual approach to reducing transmission rates and improving health outcomes among high-risk populations. While ARVs effectively manage HIV among diagnosed individuals, PrEP serves as a preventive measure for uninfected individuals at significant risk.<sup>1,2</sup> Understanding the synergies and challenges of this integration is critical to informing public health policies and interventions that can enhance access, adherence, and overall effectiveness.

Despite the proven benefits of both ARVs and PrEP, their combined use poses logistical and clinical challenges. Adherence is crucial in determining their effectiveness, as inconsistent use can lead to reduced efficacy and potential drug resistance.<sup>3</sup> Additionally, cost and accessibility remain significant barriers, particularly in low-income regions where the HIV burden is highest. Many countries struggle with securing adequate funding to provide widespread access to both treatments, further exacerbating disparities in HIV prevention and management.

The stigma surrounding HIV prevention and treatment significantly hinders the widespread adoption of these interventions. Many individuals hesitate to seek PrEP due to misconceptions and the fear of being labelled as high-risk. In contrast, others find it challenging to maintain consistent ARV use due to concerns about side effects and pill burden.<sup>4</sup> Furthermore, social determinants of health, such as discrimination, lack of adequate education, and cultural beliefs, contribute to the limited reach of these life-saving treatments. Overcoming these social and medical barriers is crucial for maximising the effectiveness of combined ARV and PrEP use. In this context, the study aims to examine the challenges and opportunities inherent in the concurrent use of ARVs and PrEP for HIV

prevention, with a focus on adherence, healthcare access, stigma, and economic impact.

## Literature review

The integration of antiretrovirals (ARVs) and pre-exposure prophylaxis (PrEP) has been widely explored as a strategy to reduce HIV transmission and improve population health outcomes.<sup>1,2</sup> ARVs have transformed the prognosis for people living with HIV by suppressing viral replication and lowering morbidity and mortality. At the same time, PrEP has proven highly effective in preventing new infections among populations at risk.<sup>1,2</sup> At first glance, combining these two interventions appears to be a straightforward way to achieve greater epidemic control.<sup>5</sup> Yet the literature reveals that the real challenge lies not in their clinical efficacy, but in the complex social, structural, and economic realities that shape how people access, use, and adhere to these interventions in everyday life.

Adherence is central to this challenge.<sup>3</sup> Irregular use of ARVs or PrEP undermines their protective benefits and increases the risk of drug resistance. Research across Kenya, Uganda, Zimbabwe, and South Africa show that while PrEP is generally acceptable among young people and women planning or experiencing pregnancy, sustaining adherence over time remains difficult.<sup>6-8</sup> Similarly, ARV adherence among people living with HIV is strongly influenced by socioeconomic conditions, including poverty, mental health, and access to healthcare.<sup>9</sup> What emerges from the literature is a complex picture. While individual factors such as side effects and pill burden play a role, they are often outweighed by structural and social determinants. Supportive social networks, perceived vulnerability to HIV, and access to confidential, convenient services can dramatically improve adherence, illustrating that adherence is less a matter of individual willpower and more a product of social and systemic context.

Stigma compounds these challenges, operating

96 as a persistent barrier to both PrEP uptake and  
97 ARV retention.<sup>4</sup> Misconceptions that PrEP  
98 encourages risky sexual behaviour, alongside  
99 fears of being labelled high-risk, discourage  
100 individuals from seeking preventive care. In  
101 contrast, HIV-positive individuals often face  
102 discrimination that erodes their engagement  
103 with treatment.<sup>4</sup> Despite this, much of the  
104 literature treats stigma descriptively,  
105 cataloguing its presence rather than  
106 interrogating how it functions across different  
107 communities and settings. Synthesising the  
108 available evidence suggests that stigma  
109 operates on multiple levels: at the service level,  
110 through breaches of confidentiality and  
111 judgmental attitudes from providers; in the  
112 community, through moralised narratives  
113 around sexuality; and through legal and policy  
114 environments that fail to protect privacy or  
115 criminalise certain behaviours. However,  
116 research evaluating which strategies effectively  
117 reduce stigma, particularly at scale, remains  
118 scarce.

119 Economic and system-level constraints further  
120 limit the effectiveness of integrated ARV–PrEP  
121 programs in the real world.<sup>10</sup> In the regions with  
122 the highest HIV burden, inconsistent drug  
123 supply, under-resourced health systems, and  
124 heavy reliance on donor funding restrict both  
125 reach and continuity of services. Global  
126 initiatives have subsidised costs, but access  
127 remains uneven, particularly for marginalised  
128 populations.<sup>11</sup> Technological innovations, such  
129 as long-acting injectable formulations, hold  
130 promise for improving adherence. Still, their  
131 potential is constrained by costs, regulatory  
132 hurdles, and the need for functional service-  
133 delivery platforms, conditions that many low-  
134 resource settings have yet to meet.

135 The literature suggests that technological  
136 solutions alone, without attention to social and  
137 systemic barriers, will not achieve the desired  
138 population-level impact. Taken together, the  
139 evidence points to a clear conclusion: structural  
140 determinants, including stigma, service design,  
141 and financing, are the primary factors shaping  
142 the effectiveness of integrated ARV–PrEP  
143 strategies, while individual biomedical barriers

144 are often secondary or mediated by these  
145 broader forces. Interventions that focus solely  
146 on individual behaviour without addressing  
147 these social and systemic conditions are  
148 unlikely to be sustainable. Three critical gaps  
149 remain: the lack of comparative studies  
150 evaluating the relative influence of structural  
151 versus individual factors across different high-  
152 risk groups; limited evidence on scalable,  
153 community based stigma reduction  
154 interventions; and scarce research on cost-  
155 effective, equitable, and sustainable delivery  
156 models. While ARVs and PrEP are clinically  
157 effective, the literature makes it clear that  
158 efficacy alone is not enough. For integrated  
159 interventions to achieve meaningful  
160 population-level impact, biomedical innovation  
161 must be paired with context-sensitive delivery  
162 models, stigma reduction strategies, and  
163 sustainable financing mechanisms. Addressing  
164 these structural and social barriers is essential  
165 not only for improving adherence but for  
166 ensuring that interventions reach those who  
167 need them most and for achieving lasting  
168 progress in HIV prevention.

169 Synthesising the evidence reveals a clear  
170 pattern: structural determinants, including  
171 stigma, service design, and financing, emerge as  
172 the primary factors shaping real-world  
173 effectiveness of integrated ARV–PrEP  
174 strategies, while individual biomedical barriers  
175 are often secondary or mediated by these  
176 broader forces. Interventions targeting only  
177 individual behaviour, without addressing these  
178 systemic factors, are unlikely to produce  
179 sustainable outcomes. Critical gaps remain: a  
180 lack of comparative studies examining the  
181 relative influence of structural versus individual  
182 factors across high-risk populations; limited  
183 evidence on scalable stigma-reduction  
184 interventions; and scarce research on cost-  
185 effective, equitable, and sustainable delivery  
186 models.

187 The study aimed to explore how structural,  
188 social, and individual factors influence the  
189 uptake and sustained use of ARVs and PrEP  
190 among high-risk populations. Specifically, the  
191 study sought to identify the key determinants

of adherence and access, examine the influence of stigma and service-delivery barriers, and generate insights to inform strategies that enhance the effectiveness of integrated HIV prevention interventions.

### Theoretical framework

This study was based on the Theory of Planned Behaviour (TPB), which explains how individual attitudes, subjective norms, and perceived behavioural control influence health-related decision-making.<sup>12</sup> TPB was particularly relevant in understanding the factors affecting adherence to ARVs and PrEP, as individuals' decisions to initiate and maintain these treatments were shaped by their beliefs about the benefits, societal pressures, and perceived ease or difficulty of adherence. The Social

Ecological Model (SEM) highlights that PrEP and ARV uptake and adherence are shaped by individual, social, structural, and policy-level factors, underscoring the need for interventions that simultaneously address personal behaviour, community norms, healthcare system barriers, and broader policy contexts.<sup>13</sup> The SEM and TPB comparison highlights the multi-level influences on ARVs and PrEP use. While the SEM examines structural and social determinants at multiple levels, the TPB concentrates on individual decision-making factors, including attitudes, subjective norms, and perceived behavioural control.<sup>2</sup> Combining these frameworks provides a more holistic understanding of the barriers and facilitators influencing HIV prevention efforts, which can be achieved, as shown in Table 1.

**Table 1. Comparison of the SEM and TPB in ARVs and PrEP use**

SEM level	TPB construct	Integration / How they complement
Individual	Attitudes	Personal beliefs and knowledge (SEM) shape attitudes and perceived benefits (TPB), influencing willingness to use ARVs/PrEP.
Interpersonal	Subjective Norms	Family, peers, and partners (SEM) affect social pressures and perceived expectations (TPB), guiding intention and uptake.
Community	Perceived Behavioural Control	Community norms, stigma, and access (SEM) influence perceived ability to act (TPB), affecting adherence and engagement.
Organisational	Behavioural Intentions	Support from healthcare institutions (SEM) facilitates behavioural intentions (TPB) by improving accessibility and affordability.
Policy	External Influences	Policies and campaigns (SEM) shape the environment, indirectly affecting attitudes, norms, and perceived control (TPB), reinforcing uptake.

### Research method

This study employed a narrative literature review to examine the challenges associated with implementing ARV and PrEP interventions for HIV prevention. A systematic search was conducted in PubMed, Scopus, Web of Science, and Google Scholar, focusing on peer-reviewed studies published between 2015 and 2025. The review targeted studies on adult populations, with particular attention to high-risk groups

such as men who have sex with men (MSM), sex workers, and serodiscordant couples, especially in sub-Saharan Africa. Key search terms included "HIV prevention," "ARVs," "PrEP," "adherence," "uptake," "stigma," and "healthcare access," enabling the identification of studies addressing both individual and structural determinants of intervention effectiveness.

Although the review prioritised contemporary

evidence, seminal theoretical works were deliberately included to provide historical and conceptual grounding. Foundational studies, such as Ajzen's theory of planned behaviour and Bronfenbrenner's ecological systems theory, offered critical frameworks for understanding how social, environmental, and individual factors interact to influence health behaviours.<sup>12,13</sup> Integrating these theoretical perspectives alongside empirical findings allowed the study to move beyond mere description of barriers and facilitators, enabling a more complex analysis of the mechanisms shaping ARV and PrEP uptake. This approach addresses a standard limitation in the field, where studies often report isolated findings without connecting them to broader behavioural or social theories.

The literature reviewed spans multiple periods, each contributing distinct insights. Early foundational studies (1979–1991) established theoretical models of health-related behaviours that continue to inform contemporary intervention design. Research from 2000–2010 explored stigma and adherence in the context of ART, revealing systemic and psychosocial barriers that persist today. Mid-period studies (2011–2020) examined the implementation of PrEP and ARV prophylaxis, including interventions targeting stigma reduction, while more recent literature (2021–2025) has focused on PrEP uptake, long-acting ART formulations, and barriers to HIV care in African contexts. Critically synthesising these findings revealed patterns across time: stigma, discrimination, and structural inequalities consistently impede adherence, while supportive social networks, confidentiality, and accessible services facilitate sustained engagement.<sup>14-20</sup>

The narrative review method was particularly suitable for this study because it enabled the integration of diverse evidence sources, including empirical research and theoretical frameworks, to identify overarching themes and knowledge gaps. Synthesising the literature in this way not only highlighted recurring barriers such as stigma, healthcare access, and

systemic limitations but also illuminated where evidence remains sparse, including scalable interventions to reduce stigma and strategies to improve equitable access.<sup>21</sup> This method, therefore, enabled a critical examination of the interplay between social, structural, and individual determinants, moving beyond descriptive reporting to provide actionable insights for enhancing ARV and PrEP implementation.

## Challenges and opportunities in the implementation of ARVs and PrEP

### Adherence and its impact on efficacy

Adherence to ART and PrEP is influenced by a complex web of interrelated factors that operate across multiple levels, highlighting the need to understand not only individual behaviour but also the social and structural contexts in which treatment occurs. At the individual level, adherence is shaped by knowledge, beliefs, and perceptions of the medications, as well as practical considerations such as pill burden and side effects (e.g., gastrointestinal discomfort, nausea, fatigue).<sup>22-24</sup> Patients who understand the mechanism of action, appreciate the importance of consistent use, and are prepared to manage side effects are more likely to maintain adherence. In contrast, those facing poorly managed side effects or complex regimens are at higher risk of discontinuation.

Moving to the interpersonal level, social support, peer influence, and patient-provider relationships critically affect adherence behaviours. Patients with strong support networks and effective communication with healthcare providers demonstrate higher adherence, while social isolation or negative peer norms can reinforce non-adherence.

At the community level, stigma, cultural norms, and local health-seeking behaviours further complicate adherence. Fear of being perceived as HIV-positive may discourage uptake of PrEP or disclosure of ART use, while entrenched societal biases exacerbate barriers even for

345 patients with optimal clinical support.  
346 Community dynamics also mediate the  
347 effectiveness of educational and counselling  
348 interventions, indicating that adherence  
349 strategies cannot be purely individual-focused.

350 Structural determinants, including healthcare  
351 infrastructure, funding mechanisms, access to  
352 clinics, and policy environments, directly  
353 constrain or enable adherence.<sup>10,20,26-30</sup> For  
354 example, shortages of trained personnel,  
355 inadequate facilities, and reliance on donor  
356 funding in LMICs can disrupt medication supply  
357 chains, creating gaps in treatment continuity.  
358 Conversely, robust infrastructure and sustained  
359 financing support consistent access,  
360 monitoring, and long-term engagement with  
361 ART and PrEP programs.

#### 362 Healthcare access and infrastructure

363 Healthcare access and infrastructure are critical  
364 factors influencing the effectiveness of ART and  
365 PrEP in both urban and rural settings. While  
366 high-income countries have successfully  
367 integrated these HIV prevention and treatment  
368 strategies into their healthcare systems, many  
369 resource-limited regions continue to face  
370 significant challenges. Rural areas often lack  
371 healthcare infrastructure, including insufficient  
372 healthcare facilities, limited access to trained  
373 medical professionals, and inadequate  
374 transportation networks for patients to access  
375 treatment.<sup>20,26</sup> This geographic disparity in  
376 healthcare access exacerbates the difficulty of  
377 providing continuous and reliable access to ART  
378 and PrEP, which are essential for HIV  
379 prevention and management. Urban areas, by  
380 contrast, typically have better healthcare  
381 infrastructure, though they face challenges,  
382 particularly with overcrowded clinics and  
383 healthcare staff shortages.<sup>26,27</sup>

384 The dependency of many low- and middle-  
385 income countries (LMICs) on donor funding has  
386 created additional challenges, particularly  
387 considering shifting global financial support.  
388 For example, a considerable portion of HIV-  
389 related financing in these regions comes from  
390 international organisations and foreign

391 governments, including those from high-  
392 income countries. However, the 2025 freeze on  
393 foreign aid, primarily affecting global health  
394 programs, severely disrupted funding for ART  
395 and PrEP initiatives.<sup>10</sup> This freeze led to cuts in  
396 essential programs aimed at HIV prevention  
397 and treatment, leaving many countries  
398 struggling to maintain their healthcare services  
399 and meet the growing demand for ART and  
400 PrEP.<sup>28</sup> These funding cuts have further  
401 exacerbated the gaps in healthcare access and  
402 continued access to treatment, particularly in  
403 rural areas where services are already limited.

404 The reduction in funding, particularly for HIV-  
405 related programs, highlights the vulnerability of  
406 healthcare systems in LMICs that rely heavily on  
407 external financial support. The inability to  
408 secure continuous funding for ARVs and PrEP  
409 can result in stockouts, disrupted treatment  
410 regimens, and reduced quality of care.<sup>26</sup>  
411 Additionally, these financial constraints limit  
412 the ability to expand healthcare infrastructure,  
413 such as building new clinics or providing  
414 additional training for healthcare workers. This  
415 is crucial to ensure sustained access to HIV  
416 care.<sup>27</sup> With the global shift in funding priorities,  
417 many LMICs are forced to rely on increasingly  
418 limited resources, further exacerbating the  
419 disparities in healthcare access between urban  
420 and rural areas.

421 Moreover, the lack of funding for clinical trials  
422 in LMICs presents a significant limitation to  
423 advancing knowledge in ART and PrEP. The  
424 discovery of new formulations, alternative  
425 delivery models, and innovative treatment  
426 options that could enhance adherence and  
427 efficacy can be impeded by a lack of investment  
428 in research and development. Clinical trials are  
429 crucial for understanding these therapies' long-  
430 term impact and identifying strategies to  
431 overcome existing barriers.<sup>29</sup> Without adequate  
432 funding for such trials, the pace of innovation  
433 slows, and the ability to address emerging  
434 challenges in HIV prevention and treatment  
435 diminishes.<sup>22</sup> Investing in healthcare  
436 infrastructure and sustainable financing models  
437 that do not rely solely on external donors is  
438 essential to address these challenges.

439 Strategies to ensure equitable access to ART  
440 and PrEP should focus on improving healthcare  
441 delivery in rural areas, reducing geographical  
442 barriers, and building local capacity to maintain  
443 these programs.<sup>10</sup> Simultaneously, augmenting  
444 domestic funding and fostering robust  
445 collaborations between international  
446 organisations and governments in low- and  
447 middle-income countries can alleviate the  
448 effects of funding reductions and enhance the  
449 long-term viability of HIV prevention and  
450 treatment initiatives.<sup>28</sup>

### 451 Stigmatisation and social barriers

452 The HIV-related stigma continues to represent  
453 a significant barrier to the uptake of ARVs and  
454 PrEP, particularly among key populations such  
455 as sex workers, men who have sex with men,  
456 and serodiscordant couples. Concerns about  
457 being mistakenly perceived as HIV-positive  
458 contribute to reluctance in seeking PrEP, as  
459 individuals fear social exclusion, ostracization,  
460 and potential harm to personal and  
461 professional relationships. Evidence from  
462 multiple studies demonstrates that stigma and  
463 discrimination manifest across familial,  
464 community, and healthcare contexts adversely  
465 affect psychological well-being, adherence to  
466 treatment, and overall health behaviours,  
467 thereby diminishing quality of life. Importantly,  
468 research also highlights that interventions  
469 specifically designed to reduce HIV-related  
470 stigma can mitigate these adverse effects,  
471 enhancing health outcomes, fostering social  
472 support, and facilitating more equitable access  
473 to prevention and treatment services. This  
474 underscores the critical need for multilevel  
475 strategies that address stigma as both a social  
476 phenomenon and a determinant of public  
477 health effectiveness.<sup>30-32</sup> On the other hand,  
478 people living with HIV who are on effective ARV  
479 treatment continue to face significant stigma  
480 despite evidence that effective treatment  
481 reduces viral load and transmission risk.<sup>33</sup> This  
482 stigma, driven by misconceptions about HIV  
483 transmission and societal biases, contributes to  
484 the marginalisation of those who need these  
485 interventions the most.

486 The literature consistently identifies social  
487 stigma as a major impediment to the uptake  
488 and sustained use of ARVs and PrEP, as it  
489 diminishes individuals' willingness to seek care  
490 and compromises adherence to prescribed  
491 regimens, undermining the effectiveness of  
492 these essential interventions. Stigma within  
493 healthcare facilities has been shown to  
494 negatively impact patient diagnosis, treatment  
495 adherence, and overall health outcomes.<sup>34</sup>  
496 Although targeted interventions exist for  
497 conditions such as HIV, mental illness, and  
498 substance use, significant gaps remain,  
499 particularly regarding other medical conditions,  
500 multi-level staff engagement, the use of  
501 interactive technologies, and the stigma  
502 experienced by healthcare workers themselves,  
503 highlighting the need for comprehensive,  
504 systemic approaches to stigma reduction.  
505 While myriad studies highlight the negative  
506 impact of stigma on treatment uptake, the role  
507 of broader structural factors, such as economic  
508 inequality, legal frameworks, and cultural  
509 norms, has received less attention. These  
510 factors exacerbate stigma and limit access to  
511 care, especially in low-resource settings. For  
512 instance, individuals in impoverished or  
513 criminalised communities may face even  
514 greater barriers to care due to legal restrictions,  
515 poverty, and lack of healthcare infrastructure.<sup>35</sup>  
516 Additionally, while some studies have called for  
517 more widespread community-based education,  
518 there is insufficient emphasis on the need for  
519 comprehensive policy changes that could  
520 create safer environments for individuals  
521 seeking HIV prevention and treatment.<sup>36</sup>

522 An essential gap identified in the literature is  
523 the lack of long-term studies examining the  
524 impact of stigma-reduction interventions on  
525 the adoption of ARVs and PrEP. While  
526 community-based education and awareness  
527 campaigns are frequently recommended,  
528 limited empirical evidence demonstrates their  
529 effectiveness in reducing stigma over time.<sup>37</sup>  
530 Moreover, the scope of these programs often  
531 fails to account for the deep-rooted cultural  
532 attitudes and misconceptions perpetuating  
533 stigma. These programs must be tailored to  
534 local contexts, considering the specific cultural,

social, and economic barriers at-risk populations face. Additionally, while there is a growing body of research on healthcare providers' role in perpetuating stigma, more work is needed to explore how to train healthcare professionals better and empower them to provide non-judgmental, supportive care.<sup>14,38</sup>

An opportunity exists to integrate stigma-reduction strategies into broader HIV prevention and care policies at both national and global levels. Governments and organisations should prioritise funding for comprehensive stigma-reduction initiatives encompassing community education, healthcare provider training, public policy advocacy, and legal reforms. Further research is needed to identify the most effective combinations of interventions to reduce stigma and improve PrEP and ARV uptake.<sup>36</sup> Additionally, interventions must go beyond reducing stigma within healthcare settings, addressing societal attitudes and the cultural dynamics that contribute to the marginalisation of at-risk populations.

A more integrated approach could include social media campaigns, peer-led education, and the involvement of influential community figures to challenge misconceptions and promote supportive attitudes toward HIV treatment and prevention. While there has been progress in recognising and addressing stigma as a barrier to HIV treatment and prevention, several gaps remain in terms of understanding its long-term impact and developing comprehensive, context-specific strategies for its reduction.

### Economic impact

The combined use of ARVs and PrEP has the potential to yield substantial economic benefits. By significantly reducing new HIV infections, ART and PrEP can alleviate the financial burden on healthcare systems. Countries that have effectively implemented these programs have witnessed notable declines in new infections, demonstrating the

potential cost savings.<sup>26,39</sup> The socioeconomic benefits of expanding access to ART and PrEP include reduced healthcare costs, increased workforce productivity, and improved quality of life for those affected by HIV. However, challenges remain regarding the affordability and accessibility of these medications, particularly in low- and middle-income countries. Several studies have examined the economic benefits and combined use of ARVs and PrEP. Expanding ART coverage to individuals in the early stages of HIV is more cost-effective than current guidelines, and targeted PrEP provision for high-risk populations in South Africa can yield cost savings.<sup>27</sup> This study highlights the potential cost savings for healthcare systems and significant socioeconomic advantages, including enhanced quality of life. Similarly, reducing HIV infections through the use of PrEP and ARVs in South Africa has been shown to lower healthcare costs and generate significant economic benefits, particularly by enhancing workforce productivity.<sup>40</sup> Furthermore, evidence from Lesotho indicates that widespread use of PrEP and ARVs among high-risk populations can generate economic savings by decreasing HIV-related health complications and enhancing workforce participation.<sup>41</sup>

Despite the clear economic benefits of ARVs and PrEP, significant challenges remain. High upfront costs, infrastructure needs, and ongoing adherence monitoring can strain health budgets, particularly in low-resource settings. Trade-offs exist between short-term investment and long-term savings, and the literature shows conflicting estimates of cost-effectiveness across populations and contexts. Blended funding models, combining domestic budgets, international aid, and outcome-based incentives, offer viable solutions to support sustainable and equitable access.

The combined use of ARVs and PrEP offers several economic benefits, such as reducing HIV transmission, lowering long-term healthcare costs, and improving workforce productivity. By preventing new HIV infections, PrEP helps reduce the number of people requiring ARV

629 treatment, saving healthcare expenses.<sup>26, 39</sup> It  
630 also serves as a cost-effective prevention  
631 strategy, promoting better health outcomes,  
632 life expectancy, and quality of life.<sup>40</sup>

633 Additionally, it empowers at-risk groups, such  
634 as sex workers, by keeping them healthy and  
635 productive, thereby improving their economic  
636 standing.<sup>41</sup> However, these benefits come with  
637 economic challenges, including high upfront  
638 medication costs (Table 2 below), healthcare  
639 personnel, and infrastructure.<sup>39</sup> Funding  
640 sustainability remains a concern, particularly in

641 low-resource settings that rely heavily on  
642 international aid.<sup>26</sup> Ongoing adherence and  
643 monitoring requirements add to healthcare  
644 expenses, while stigma and discrimination can  
645 hinder PrEP uptake, leading to indirect costs like  
646 lost productivity.<sup>40</sup> Furthermore, inequality in  
647 access to ARVs and PrEP due to economic  
648 disparities may result in uneven health  
649 outcomes, and the high cost of medications  
650 remains a barrier.<sup>41</sup> Lastly, the potential for  
651 misuse of these treatments could lead to drug  
652 resistance or unnecessary costs, further  
653 complicating the economic landscape, Table 2.

654 **Table 2. Economic benefits and challenges of combined use of ARVs and PrEP**

Economic benefits	Economic challenges
<b>Reduction in HIV transmission</b> Preventing HIV infections through PrEP reduces the long-term costs associated with treating HIV.	<b>High upfront costs</b> Substantial initial costs for medications, healthcare personnel, and infrastructure.
<b>Lower HIV-related healthcare costs</b> PrEP reduces new HIV cases, minimising long-term treatment costs for ARV users.	<b>Sustainability of funding</b> Ongoing funding is required, especially in low-resource settings dependent on international aid.
<b>Improved Workforce Productivity</b> Preventing new HIV infections helps maintain a healthier workforce, boosting economic productivity.	<b>Adherence and monitoring costs</b> Regular health check-ups, HIV testing, and adherence monitoring add to the healthcare costs.
<b>Cost-effective prevention strategy</b> PrEP is a cost-effective method to prevent HIV, reducing future medical expenses associated with treatment.	<b>Stigma and discrimination</b> The stigma surrounding HIV and PrEP can decrease uptake, leading to indirect costs such as lost productivity.
<b>Improved life expectancy and quality of life</b> Using ARVs and PrEP improves health outcomes, reducing overall healthcare burdens.	<b>Inequality in access</b> Economic disparities may limit access to ARVs and PrEP, contributing to uneven health outcomes and higher costs in some regions.
<b>Economic empowerment of at-risk groups</b> People at risk (e.g., sex workers) can remain healthy and productive, improving their economic situation.	<b>Pharmaceutical costs</b> Costs of ARV and PrEP medications remain high, especially in areas without subsidies or low-cost alternatives.
	<b>Potential for misuse</b> Incorrect use or over-prescription of ARVs and PrEP may lead to drug resistance or unnecessary costs.

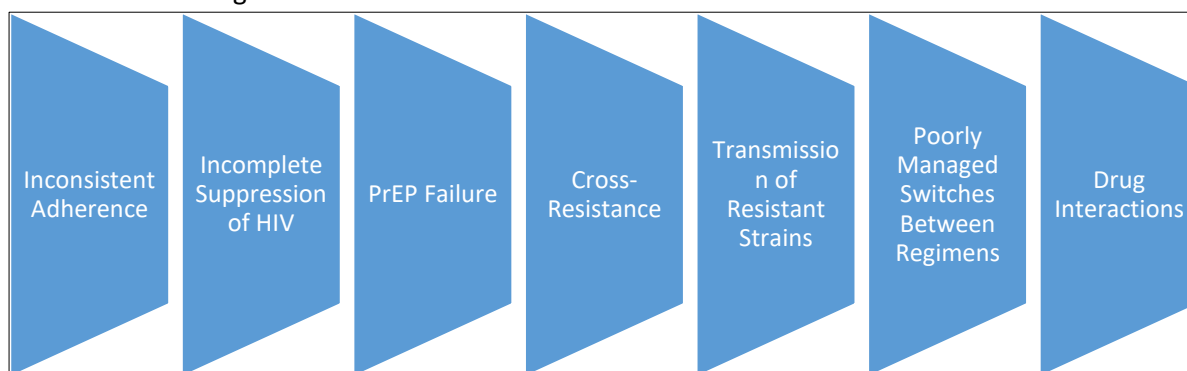

### 655 **Drug resistance and long-term sustainability**

657 The simultaneous use of ARVs and PrEP raises  
658 concerns about the risk of drug resistance,  
659 particularly when either medication is taken  
660 inconsistently. Several factors related to ARVs  
661 and PrEP raise concerns about the risk of drug  
662 resistance, particularly when either medication  
663 is taken inconsistently, as depicted in Figure 2

664 below. Resistance to these drugs could  
665 undermine both treatment and prevention  
666 efforts, making it critical to develop strategies  
667 that ensure adherence and minimise the  
668 emergence of resistant HIV strains.<sup>42</sup>  
669 Monitoring for drug resistance and developing  
670 smaller pill formulations and alternative  
671 delivery models are essential to sustain the  
672 effectiveness of both ARVs and PrEP in the

673 long term.<sup>29</sup> Ongoing research is needed to  
674 understand the long-term effects and

675 sustainability of dual therapy, Figure 1.

676  
677 **Figure 2: Factors increasing drug resistance risk with ARVs and PrEP**

## 678 Key findings and discussion

### 680 The Adherence Paradox

681 Adherence to ART and PrEP is shaped by a  
682 complex interplay of individual, social, and  
683 structural factors. While pill burden and side  
684 effects influence individual behaviour, evidence  
685 shows that patients who understand how their  
686 medication works, the importance of consistent  
687 use, and the consequences of non-adherence  
688 are more likely to follow their regimens.<sup>24</sup> High-  
689 risk populations face additional challenges  
690 where misconceptions, stigma, and limited  
691 healthcare literacy reduce engagement.<sup>24</sup>  
692 Structural barriers, including restricted access  
693 to healthcare facilities, shortages of trained  
694 personnel, and reliance on donor funding,  
695 further complicate adherence, particularly in  
696 rural areas of LMICs.<sup>20,26-28,39</sup> Urban centres,  
697 although better resourced, still contend with  
698 overcrowded clinics and staff shortages,  
699 creating gaps in patient monitoring and  
700 continuity of care.<sup>26,27</sup> These findings suggest  
701 that adherence cannot be treated as an isolated  
702 behaviour; it emerges from a dynamic network  
703 of clinical, social, and systemic determinants.  
704 Evidence varies in strength, with some studies  
705 quantifying structural impacts and others  
706 relying on qualitative patient reports,  
707 highlighting the need for integrated, multi-  
708 method approaches.

### 709 The false economy of underfunding

710 Economic analyses indicate that combining ART

711 and PrEP yields substantial long-term savings by  
712 preventing new infections, reducing chronic  
713 care costs, enhancing workforce productivity,  
714 and improving quality of life.<sup>26,39,40,41</sup> Targeted  
715 PrEP provision for high-risk populations and  
716 early ART initiation have demonstrated  
717 measurable cost benefits, particularly in South  
718 Africa.<sup>27</sup> Yet short-term funding limitations,  
719 especially in donor-dependent LMICs, create  
720 vulnerabilities. Disruptions in international  
721 support, such as the U.S. freeze on foreign aid  
722 in early 2025, have led to stockouts and  
723 disrupted treatment regimens, paradoxically  
724 generating long-term economic and health  
725 burdens by increasing transmission and  
726 complicating treatment.<sup>10,28</sup> Adherence  
727 monitoring, infrastructure development, and  
728 personnel training. However, costly upfront,  
729 they are economically justified when  
730 considering the avoidance of downstream  
731 healthcare burdens.<sup>26,28,40</sup> Blended funding  
732 models that integrate domestic financing,  
733 international aid, and performance-based  
734 incentives offer a pragmatic path to  
735 sustainable, equitable access, though evidence  
736 of their long-term effectiveness remains  
737 limited.<sup>26, 28</sup>

### 738 Stigma as a unifying barrier

739 Stigma constitutes a primary barrier to ART and  
740 PrEP uptake, directly undermining public health  
741 investments<sup>30-32</sup> It affects diverse populations,  
742 including sex workers, men who have sex with  
743 men, and serodiscordant couples. Individuals  
744 may avoid PrEP due to fear of being perceived

745 as HIV-positive, while persistent societal biases  
746 hinder ART adherence even when viral  
747 suppression is achieved.<sup>33</sup> Interventions such as  
748 community education, healthcare provider  
749 training, and policy advocacy show promise in  
750 reducing stigma.<sup>34,35,37,38</sup> Yet, they often fail to  
751 address structural and cultural factors poverty,  
752 criminalisation, and entrenched social norms  
753 that perpetuate exclusion.<sup>34,25,36-38</sup> Moreover,  
754 the long-term efficacy of stigma-reduction  
755 programs remains poorly understood,  
756 highlighting the need for sustained, context-  
757 specific strategies that integrate societal  
758 attitudes, healthcare practices, and supportive  
759 policies.

### 760 Resistance and clinical implications

761 Concurrent use of ART and PrEP raises concerns  
762 about drug resistance, particularly under  
763 inconsistent adherence.<sup>42</sup> Resistance can  
764 compromise both treatment and prevention  
765 efforts, emphasising the need for adherence  
766 strategies, smaller pill formulations, and  
767 alternative delivery models.<sup>29</sup> While existing  
768 studies provide valuable insights, long-term  
769 data on resistance patterns and the efficacy of  
770 combined therapy remain scarce, underscoring  
771 the need for longitudinal research to inform  
772 clinical and public health interventions.

### 773 Study limitations and future research

774 This study has several limitations that may  
775 affect interpretation and generalisability.  
776 Variations in study quality and context-specific  
777 findings, including conflicting evidence on  
778 adherence, stigma, and economic outcomes,  
779 limit the applicability of results across  
780 populations. Additionally, the sample may not  
781 fully represent diverse populations or contexts,  
782 determining the relevance of the findings to  
783 broader settings. The study relied primarily on  
784 secondary data from the literature. It did not  
785 incorporate quantitative studies, which limits  
786 insight into subjective experiences, social  
787 dynamics, and the barriers influencing ARV and  
788 PrEP use. Moreover, the study's cross-sectional  
789 design limits the ability to assess long-term  
790 behavioural changes or causality between the

791 variables. To address these limitations, future  
792 research should adopt a mixed-methods  
793 approach, combining quantitative surveys with  
794 qualitative interviews or focus groups to  
795 provide a richer, more holistic view of the  
796 factors influencing ARV and PrEP use.  
797 Expanding the sample to include diverse  
798 populations from varied geographical, social,  
799 and economic backgrounds would improve the  
800 generalizability of the findings. Furthermore,  
801 undertaking longitudinal studies would provide  
802 insights into the evolution of attitudes and  
803 behaviours towards ARVs and PrEP, facilitating  
804 a more thorough understanding of the long-  
805 term efficacy of these interventions.

806 Governments and healthcare providers should  
807 consider these research recommendations to  
808 design more tailored and effective HIV  
809 prevention strategies, ensuring that  
810 interventions are accessible and contextually  
811 appropriate for different populations.

### 812 Study recommendations

813 To enhance the effectiveness of ART and PrEP,  
814 future interventions must prioritise patient  
815 education and health literacy. Educating  
816 patients about the importance of adherence,  
817 the risks associated with non-compliance, and  
818 how their treatment works can improve long-  
819 term outcomes. Regular counselling and  
820 ongoing education tailored to high-risk  
821 populations, where stigma and misconceptions  
822 abound, should be emphasised to ensure  
823 continuous adherence. Additionally, healthcare  
824 access and infrastructure should be  
825 strengthened, particularly in resource-limited  
826 and rural areas, to reduce geographical barriers  
827 to treatment. Investments in healthcare  
828 infrastructure, sustainable financing, and local  
829 capacity-building are necessary to support ART  
830 and PrEP programs, reduce reliance on external  
831 aid, and ensure long-term program viability.

832 Addressing the stigma surrounding HIV  
833 treatment and prevention is another critical  
834 area for improvement. Initiatives aimed at  
835 reducing stigma within healthcare settings and  
836 society should be integrated into national and

837 global HIV policies. Developing culturally  
838 relevant, community-driven stigma-reduction  
839 strategies, alongside training healthcare  
840 providers to offer non-judgmental care, could  
841 significantly improve uptake and adherence.  
842 Furthermore, more research on the long-term  
843 impact of stigma-reduction interventions and  
844 on the broader structural factors that  
845 perpetuate stigma is needed to inform future  
846 strategies.

847 Economically, the combined use of ARVs and  
848 PrEP can yield substantial benefits by reducing  
849 HIV transmission, lowering healthcare costs,  
850 and improving workforce productivity.  
851 However, challenges such as high medication  
852 costs, funding sustainability, and access  
853 inequalities must be addressed. Policymakers  
854 should explore innovative funding models and  
855 enhance access to affordable medications,  
856 especially in low-resource settings. Monitoring  
857 for drug resistance and developing alternative  
858 delivery methods could also ensure the long-  
859 term sustainability of these treatments while  
860 minimising the risk of resistance and enhancing  
861 overall treatment efficacy.

## 862 Conclusion

863 This study offers important insights into the  
864 various factors that affect the use of ARVs and  
865 PrEP, highlighting key implications for  
866 enhancing HIV prevention strategies. The  
867 findings underscore the importance of  
868 considering structural factors (such as  
869 healthcare access and community support) and  
870 individual behaviours (including attitudes and  
871 perceived control) when designing  
872 interventions. Although the study's limitations  
873 highlight the need for further research,  
874 addressing these gaps in future studies will help  
875 refine HIV prevention strategies and ensure  
876 that public health initiatives are comprehensive  
877 and practical. Enhancing research  
878 methodologies and incorporating varied  
879 perspectives will foster a more inclusive and  
880 sustainable approach for addressing HIV/AIDS.
