Abstract

*Ocimum sanctum*, commonly known as Tulasi in Nepal, is a pharmacologically important plant due to its active constituents. In this work, extraction was carried out in hexane, chloroform and methanol solvents and their phytochemical screening was performed. Total phenolic and flavonoid contents in the plant were measured by Folin-Ciocalteu colorimetric method and aluminum chloride colorimetric method respectively. Antioxidant activity of the extracts was evaluated using 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging assay. Alkaloids, flavonoids, tannins, glycosides, polyphenols, terpenoids, tannins and steroids are mainly found in the extracts. Based on the result obtained, the plant posses a significant amount of total phenolic and total flavonoid content. Both phenolic and flavonoid contents were highest in methanol extract, followed by chloroform and hexane extract. Antioxidant activity of the extracts as ascorbic acid standard (IC\(_{50}\) value = 41.34 µg/mL) was in the order of methanol extract (IC\(_{50}\) value = 47.73 µg/mL) > chloroform extract (IC\(_{50}\) value = 79.46 µg/mL) > hexane extract (IC\(_{50}\) value = 94.68 µg/mL). The extent of the antioxidant activity of the plant is following the number of total phenolics and flavonoids present in it.

Keywords: *Ocimum sanctum*, extract, phenolic content, flavonoid content, antioxidant activity

Introduction

Plants are primary sources of medicines since ancient times. Medicinally important plants contain the various bioactive secondary metabolites having several therapeutics importances [1]. Medicinal plants are advantageous for various treatments due to their fewer side effects, less expensive, efficacy and availability throughout the world. In Ayurveda, *Ocimum sanctum* Linn. has been used for its healing properties of the mind, body, and spirit [2]. *Ocimum sanctum*, commonly known as Tulasi or Tulsi in Nepali and Holy Basil in English, is the aromatic plant in the family Liliaceae [3]. It is a branched and erect herb having hair all over [4]. It is the most sacred plant among all the herbs found in Nepal. Different parts of *O. sanctum* (leaves, stems, flowers, roots, seeds and even whole plant) have been used for the treatment of bronchitis, arthritis, malaria, diarrhea, dysentery, skin disease, chronic fever, insect bite etc, [5,6]. Evidence shows that *O. sanctum* cures the physical, chemical, psychological, and metabolic stress of the human body by a unique combination of pharmacological actions [7]. It controls metabolic stress through normalization of blood glucose, blood pressure and lipid levels and psychological stress by enhancing positive effects on memory through anxiolytic and antidepressant properties [8]. *O. sanctum* also possesses anti-infertility, anticancer, anti-diabetic, antifungal, antimicrobial, hepatoprotective, antispasmodic, analgesic and cardioprotective properties [9]. The plant is a rich source of essential oil and bioactive phytochemical constituents like alkaloids, flavonoids, terpenoids, phenolics, tannins and saponins [1,10]. Polyphenols and flavonoids present in this plant are largely responsible for imparting various therapeutic values including antioxidant potentiality. Antioxidants are the chemical compounds that can scavenge free radicals that are generated in the body due to various reasons. Free radicals are capable of attacking the healthy body cells which may lead to cellular damage, several diseases and disorders [11].
Materials and Methods

Plant materials

Fresh and matured leaves of *Ocimum sanctum* were collected from Dhading, Nepal, in the December month of 2018. The plant was authenticated at the Department of Botany, Amrit Campus, Kathmandu, Nepal. The collected leaves were cleaned, shade dried and powdered and stored in airtight bottles.

Extraction

The dried and powdered leaves of *Ocimum sanctum* were extracted separately with three different solvents hexane, chloroform and methanol by using soxhlet apparatus. Accurately weighed 50 g powdered leaves were filled in a thimble and placed in the central assembly of the soxhlet apparatus. Accurately measured 250 mL solvent such as hexane, chloroform, and methanol was added separately to a 500 mL round bottom flask. The extraction was done at 68 ºC, 61 ºC, and 64 ºC for six hours respectively. After that, the obtained liquid extracts were concentrated using a rotary evaporator (IKA RV 10 digital). The percentage yield (w/w) of the crude extracts was calculated and stored in the refrigerator at 5 ºC till required for analysis.

Phytochemical screening

The hexane, chloroform, and methanol extracts (1 gm) were completely dissolved in 100 mL of their mother solvents for the stock solution preparation. The obtained stock solutions were subjected to phytochemical screening by following standard protocols [12,13].

Determination of total phenolic content

Total phenolic content was determined by the modified Folin-Ciocalteu colorimetric method based on the oxidation-reduction reaction [14-16]. The stock solutions of hexane, chloroform, and methanol extracts were prepared by dissolving 100 mg in 1 mL of their mother solvents. Serial dilutions were carried out to get the concentrations of 0.125, 0.25, 0.5 and 1.0 mg/mL. 1.0 mL of each solution was taken in a test tube, and 5 mL of 10% Folin-Ciocalteu reagent was added on it. After five minutes, 4 mL of 7% Na₂CO₃ was added to the mixture. The mixture was shaken well and allowed to incubate for 30 minutes at 40 ºC for blue color development. The absorbance was measured at 760 nm against blank using a double beam UV/Visible spectrophotometer (UV professional double beam, Shimadzu made). Total phenolic content was determined as mg/g of gallic acid equivalent (mg of GAE/g of dry extract) by using the equation obtained from a standard gallic acid calibration curve \(y=0.014x\), \(R^2=0.9951\). Values are presented as the mean ±SE of each three replicates.

Gallic acid calibration curve

The Gallic acid calibration curve was prepared by the Folin-Ciocalteu reagent method with modification. Gallic acid (10 mg) was dissolved in methanol (1 mL). It was a concentration of 10mg/mL. It was diluted by adding methanol to prepare serial concentrations 10, 25, 50 and 100µg/mL. The above same procedure was followed for gallic acid standard. The absorbance was measured for all standard solutions by using UV-spectrophotometer (UV professional double beam, Shimadzu made) at a constant wavelength of 760 nm [17].

Determination of total flavonoid content

The total flavonoid content of extracts was estimated by the aluminum chloride colorimetric method by following standard protocol by Hossain *et al.* and Chandra *et al.* with some modifications [18-20]. Stock solutions of all three extracts were prepared by dissolving each extract (100mg) separately with their mother solvents. Serial dilutions were carried out to get the concentrations of 0.125, 0.25, 0.5 and 1.0 mg/mL. Different concentrations of different extracts (1 mL) were taken in different test tubes and added double distilled water (4.0 mL) and 5% sodium nitrate (0.3mL) then mixed. All the test tubes were kept in a dark place for 6 minutes. Then 10% aluminum chloride (0.3 mL) was added into the test tube and wait for 5 min in the dark for complete reaction. Finally, 2 mL of 1M NaOH was added to the mixture. Immediately, the volume of the mixture was made up to 10 mL by the addition of 2.4 mL double distilled water and mixed thoroughly. The absorbance of all samples was measured at a fixed wavelength of 510 nm using a UV/Visible spectrophotometer (UV professional double beam, Shimadzu made). Quercetin standard was used for the calibration curve. Total flavonoid content was determined as mg/g of quercetin equivalent (mg of QE/g of dry extract) by using the equation obtained from a standard quercetin calibration curve \(y=0.0081x\), \(R^2=0.9744\). All the
determinations were carried out in triplicate and the results were averaged.

**Antioxidant activity test**

The free radical scavenging activity was measured by using DPPH (1,1-diphenyl-2-picryl hydrazyl) radical scavenging assay as described by Hossain et al. and Sharma et al. with some modifications [18,21]. Different concentrations (10, 30, 50, 70, 90 &110 μg/mL) of extracts and ascorbic acid (positive control) were prepared. From each solution, 1 mL of each solution was taken in an Eppendorf tube and 1 mL of the 0.2 mM DPPH solution was added. The tubes were shaken and allowed to stand at 30 ºC for half an hour. The absorbance was taken on a UV-Visible spectrophotometer (UV professional double beam, Shimadzu made) at 517 nm. Lower the absorbance of the reaction mixture indicates higher free radical scavenging activity. Measurement was performed in triplicate and the percentage radical scavenging activity was calculated using the following equation:

\[
\text{% radical scavenging activity} = \left(\frac{\text{Abs. control} - \text{Abs. sample}}{\text{Abs. control}}\right) \times 100\%
\]

The standard graph of concentration versus the percentage of free radical scavenging activity was plotted. Based on this graph, the IC\textsubscript{50} value of each extract was calculated and these values were compared. The IC\textsubscript{50} value closest to that of ascorbic acid is considered to have the best antioxidant property [22].

**Results and Discussion**

**Extraction and phytochemical analysis**

The yields of hexane, chloroform, and methanol extracts of the leaves of *Ocimum sanctum* were 3.5%, 10.50%, 15.25% respectively. The percentage yield of extract increases with the increase of the polarity of the solvent. The qualitative analysis of the three different extracts (Table 1) showed the presence of different phytochemical constituents. Flavonoids and terpenoids were present in all extracts. Alkaloids, glycosides, polyphenols, tannins, and steroids were present in chloroform and methanol extract. Proteins were found in methanol extract only. The presence of these metabolites in the plant helps to show antioxidant potency and other biological properties [23].

The result showed significant total phenolic and flavonoid content in plant extracts. The number of total phenolic content was determined as quite high in methanol extract of *O. sanctum* (180.21 ± 0.89 mg GAE/g). It was found that total flavonoid content is also found highest in methanol extract (67.11 ± 0.43 mg QE/g) followed by chloroform and hexane extract. The polarity of the solvents may affect the concentration of TPC and TFC. The high concentration of phenolic and flavonoid components in the plant, may effectively eliminate free radicals and they directly contribute as antioxidants [23,24]. The sufficient amount of total phenolic and total flavonoid content in *O. sanctum* has been reported by

**Total phenolic content (TPC) and total flavonoid content (TFC)**

In the present study, the total phenolic and flavonoid contents of three different extracts of *Ocimum sanctum* were determined. TPC and TFC were calculated by extrapolation from the calibration curve prepared from gallic acid and quercetin concentrations, respectively. Table 2 displays the TPC and TFC of three different extracts of *Ocimum sanctum*.

**Table 2: Total phenolic and total flavonoid contents of different extracts of Ocimum sanctum leaves**

| Data expressed as mean ± SE of three replicates |
several authors also [25-29].

**DPPH radical scavenging activity**

DPPH assay was carried out to analyze the antioxidant activity of the plant by using ascorbic acid as standard. In this assay, different concentrations of different extract solutions and ascorbic acid solutions were incubated at room temperature and their absorbance was recorded by spectrophotometer. The percentage of free radical scavenging at different concentrations and IC\(_{50}\) values of each extract and ascorbic acid were calculated and the results are presented in table 3 and figure 1.

The figure above shows that percentage inhibition of DPPH free radical by extracts of *O. sanctum* was found to be near to ascorbic acid which was taken as standard. IC\(_{50}\) values of three extracts were also found to be close to the standard ascorbic acid taken.

So, methanol extract of *O. sanctum* is more potent in terms of antioxidant activity. It also contains the highest amount of TPC (180.21 ± 0.89 mg GAE/g of dry extract) and TFC (67.11 ± 0.43 mg QE/g of dry extract). The high antioxidant activity of the methanol extract may be due to the presence of phytochemicals such as flavonoids, polyphenols, and tannins. This work is also supported by previous reports that flavonoids, polyphenols, and tannins found in plants have significant antioxidant activity [25,26]. This shows that *O. sanctum* leaves can act as a very good option in the field of medicine based on the antioxidant property of natural products chemistry. Previous studies from various researchers reported *O. Sanctum* as a protective antioxidant supplement [30,32]. Kelm *et al.* isolated six major compounds from *O. sanctum* which are responsible for exhibiting antioxidant activity by the plant [32].

**Conclusion**

In the present investigation, extractions from *Ocimum sanctum* leaves powder has been carried in hexane, chloroform and methanol solvents. Phytochemical screening of the extracts revealed the presence of alkaloids, flavonoids, tannins, glycosides, polyphenols, terpenoids, tannins and steroids. The plant possesses a high amount of total phenolic and total flavonoid contents. DPPH scavenging activity showed that the plant possesses high antioxidant properties. Among all three extracts, the IC\(_{50}\) value of methanol extract was the lowest and closest (47.73 µg/mL) to that of standard ascorbic acid (41.34 µg/mL). The significant potency of the extracts of *O. sanctum* leaves can act as a very good option in the field of medicine based on the antioxidant property of natural products chemistry.
sanctum leaves as antioxidant agents may be due to the presence of high phenolic and flavonoid contents.
