A Comparative Study of patients, Undergoing Transurethral Resection of Prostate Gland With Or Without Otis Urethrotomy Before Surgery – A Single Institution Experience

Shrestha NM

ABSTRACT
Background: Transurethral resection of prostate (TURP) is considered as the gold standard surgical treatment for Benign prostatic Hyperplasia (BPH). Among many post TURP complications, urethral stricture is one of the most dreaded urological complication, which may result in life long misery. The present study aimed to report the outcomes of Otis urethrotomy to prevent urethral stricture before TURP. Method: This was a comparative study between two equal groups of 100 patients who met inclusion criteria. Study conducted in the department of surgery, Urology unit, Nepalgunj Medical College from 2014 May to 2016 April. In group A, included all the patients underwent TURP without Otis urethrotomy and in group B, included all patients underwent TURP after doing Otis Urethrotomy. The patients were evaluated for evidence of urethral stricture formation. Result: In Group A, 20 patients out of 100(20%) developed urethral stricture whereas in Group B, 8 patients out of 100(8%) developed urethral stricture. The rate of Urethral Stricture in Group A is significantly more than in Group B (p<0.05). Conclusion: The incidence of urethral stricture formation can be significantly reduced by doing Otis urethrotomy before TURP than TURP alone.

Key words: TURP, otis urethrotome, urethrotomy, stricture

INTRODUCTION
TURP is considered as the gold standard surgical treatment for BPH throughout the world. In the 1986 National Health Survey, 96% of the patients undergoing prostate surgery for BPH had TURP. It was estimated that 350,000 Medicare patients had a TURP that year1. First TURP was reported in 1932. In 1876, the American Fessenden N. Otis developed a dilating urethrotome with a calibrating device.

An Otis urethrotomy is the blind transurethral incision of the urethra by an Otis urethrotome. After insertion of the Otis urethrotome, the urethra is dilated to the desired width and a blade cuts the stretched urethra at the 12 o’clock position. The Otis urethrotomy is reserved for the palliative treatment of long-segment strictures of the male urethra or to treat proximal narrowing of the female urethra. Otis urethrotomy is also performed before the use of resectoscopes (>26 CH) in a narrow urethra to prevent ischemic damage2.

Like other surgeries, it is also not free from complications, such as TURP syndrome, urinary incontinence, bladder perforation, haematuria, septicemia. Urethral stricture is one of the late complication following TURP3. The urethra receives considerable trauma from instrumentation during TURP. In most cases, the urethra heals without sequels. However, in <10% of patients the urethra heals by forming scar tissue that causes blockage of the lumen. This complication is treated with dilation or transurethral incision to re-establish urethral patency4.

This study compares the incidence of urethral stricture formation in patients undergoing TURP with or without using Otis urethrotomy before surgery.

MATERIAL AND METHODS
It is comparative study conducted from May 2014 to April 2016 in the department of surgery, urology unit, in NGMC. The patients, who met inclusion criteria, were divided into two group. Group A consisted the patients who underwent TURP alone and group B consisted those who underwent Otis urethrotomy before TURP.

Inclusion criteria for the present study were as follows:
I. Patients who have no previous history of catheterization, urethral manipulation or trauma.
II. Patients who did follow up.
III. Patients who have no previous history of urethritis.
IV. Patients with no history of urethral stricture, meatal stenosis or passage of stone from urethra.
V. Patients with no additional procedure during TURP like per urethral cystolithotripsy or litholapaxy.

All patients were examined with Ultrasonography, x-ray, kidney ureter bladder (KUB), urine for routine, culture and sensitivity, prostate specific antigen. In some performed cystoscopy also. Further the patients were studied for clinical history and clinical examination. Routine laboratory test for operation were done.

Ultrasonography (USG), urine test, cystoscopy are shown in the lower urinary tract syndrome (LUTS) underwent through the findings in both groups of patient having complain with LUTS were detected. All patients in follow up who complained of urethral stricture formation. All the patients in follow up who diagnosed with urethral stricture were treated with filliform follower urethral dilation and further self calibration.

**Statistical analysis:**
Data analysis was performed with the program statistical package for social science (SPSS version 17.0). The qualitative variables were presented as frequency and percentage. For the parametric test of two independent group data, independent t-test was used. A p-value less than 0.05 was considered statistically significant.

**RESULT**
Total number of patients were 200, one hundred in each group. The age ranged from 62–79. The types and the respective rate of findings in both groups of patient having complain with lower urinary tract syndrome (LUTS) were detected through Ultrasonography (USG), urine test, cystoscopy are shown in the Table-I. Furthermore, the common site of ureteral stricture is shown in the Table-II.

**DISCUSSION**
Enlargement of prostate gland is one of the main cause of bladder outlet obstruction in old age male patient. Due to associating other disease like chest infection and heart disease in this group, operating is so challenging. Since the TURP has developed, the complication has reduced in comparison to open surgery. But still it has also complications. Urethral stricture formation is one of the late complication in any prostate surgery but TURP has reduced the incidence but still ranges between 7-9% 6,7. But the routine use of internal Otis urethrotomy before TURP reduces the chance of urethral stricture formation 8,9.

This study also showed the advantages of Otis urethrotomy before TURP. By using Otis urethrotome decreases the rate of urethral stricture is due to increment of urethral caliber and decreases the chance of urethral injury caused by stretching and friction from wide resectoscope sheath. Although trauma during surgery is the commonest cause, but post operative urethritis caused by indwelling catheter or infection can also result in stricture formation. This is particularly true if the catheter is of large size and keeps for longer time. In addition the incidence of stricture formation is related to the size of gland and duration of resection 10.

The present study showed the commonest site of urethral stricture formation was at meatus and this finding is supported by the study of Bilal H and Walton JK et. studies 11,12.

**CONCLUSION**
This study revealed that performing Otis urethrotomy before TURP can reduce the incidence of urethral stricture formation significantly than TURP alone.

RESULT

The age ranged from 62–79. The types and the respective rate of findings in both groups of patient having complain with lower urinary tract syndrome (LUTS) underwent Ultrasonography (USG), urine test, cystoscopy to confirm the site of urethral stricture formation. All the patients in follow up who were diagnosed with urethral stricture were treated with filliform catheter removed after 48 hours, patient discharged on third day of treatment.

All patients were followed up. Patients who complained of urethral stricture were treated with filliform dilation. Brit J Urol,1984;56:202.

The present study showed the commonest site of urethral stricture is meatus. The stricture formation was at meatus and this finding is supported by the study of Bilal H and Walton JK et. studies. The incidence of stricture formation is related to the size of urethral caliber and duration of resection. The results of the present study showed that performing Otis urethrotomy before TURP can reduce the incidence of urethral stricture formation.

This study revealed that performing Otis urethrotomy before TURP can reduce the incidence of urethral stricture formation. The present study showed the commonest site of urethral stricture is due to increment of urethral caliber and stricture formation is one of the late complications in any open surgery. But still it has also complications. Urethrotomy before TURP reduces the chance of urethral stricture formation.

CONCLUSION

The present study showed that performing Otis urethrotomy before TURP can reduce the incidence of urethral stricture formation. This study also showed the advantages of Otis urethrotomy by the study of Bilal H and Walton JK et. studies. The incidence of stricture formation is related to the size of urethral caliber and duration of resection.
