Association between Psoriasis and Obesity

Pandey S¹, Jha S², BK S³, Pokharel K⁴

ABSTRACT

Background: Psoriasis is primarily a chronic skin disease, the course being punctuated by remissions and relapses. Research has shown that hypertension, obesity, heart failure and diabetes are significantly more common in patients with psoriasis. Obesity is associated with severe psoriasis and is reported about twice as frequently among psoriasis patients as in the general population. In recent years many reports have demonstrated an association between psoriasis and metabolic syndrome. Objectives: The aim of this study was to identify the prevalence of obesity in patients with psoriasis and compare it with that of non-psoriatic population.

Material and Method: This study is a case control hospital based study conducted in the Department of Dermatology, Venereology and Leprology of Nepalgunj Medical College Teaching Hospital, Kohalpur between May 2017 to October 2018. Total 56 cases of psoriasis and similar number of healthy age and sex matched controls were enrolled in the study after taking written consent. Detailed history and physical examination was performed with measurement of body mass index which was recorded. Statistical analysis was done using SPSS 20. Result: The results of the study which included 56 patients with psoriasis and 56 subjects without psoriasis. Among them 26 male and 30 female in study population and 25 male and 31 female in control group. The mean age was 41.68±19.04 years in study population and 39.46 ±16.27 years in control group. Duration of disease ranged from 2 months to 360 months and PASI score ranged from 4.4 to 28.2 with mean PASI score 11.02±5.4. BMI in cases ranged from 16.7 to 34.2 with mean 24.3±4.3 and in controls it ranged from 15.5 to 29.1 with mean 21.9±3. Mean BMI was significantly higher in cases than controls.

Conclusion: The result of this study supports the significantly higher prevalence of obesity in study population than control group.

Keywords: Psoriasis, obesity

INTRODUCTION

Psoriasis is a common skin disorder affecting approximately 1-6% of the population in the world. Psoriasis is a chronic skin disease characterized by inflammatory cell infiltration, hyper proliferation of epidermal cells and dilated microvessels¹. Studies suggest that the disease has bimodal onset, the first peak at the age between 16-22 years and later at 57-60 years of age². Psoriasis tends to occur equally in both the sexes. studies have shown that the mean age of onset is at 33 years of age and 75% of cases occurs before the age of 46 years³.

The etiopathogenesis of psoriasis is not well understood and various etiological factors have been thought to cause the disease in combination including genetic factors, trauma, infection, environmental factors, drugs, endocrine factors, sunlight, metabolic factors, alcohol, cigarette, and psychological factors⁴. It is characterized by exaggerated and disordered epidermal cell proliferation and keratinization. A host of abnormalities seen in psoriasis, like increased levels of cyclic - adenosine monophosphate (CAMP), epidermal growth factor receptor binding, protein kinase C and transforming growth factors collectively point to a disturbance in T cell function. Currently, the most accepted hypothesis is that psoriasis is an immune-mediated inflammatory skin disease that manifests in a genetically predisposed person exposed to certain environmental agents or triggers. This view has been reinforced by the efficacy of various immunomodulatory agents in the treatment of psoriasis⁵.

Obesity is associated with severe psoriasis and is reported about twice as frequently among psoriasis patients as in the general population. In recent years many reports have demonstrated an association between psoriasis and metabolic syndrome. Metabolic syndrome is combination of: Central obesity, diabetes mellitus type 2, hypertension and dyslipidaemia⁶.

There are several evidences which indicate that psoriasis is closely associated with obesity and hypertension. Herron et al. found that obesity is almost twice as prevalent in patients with psoriasis as in general population⁷.

METHODS

This study is a hospital based Case control study conducted in the Department of Dermatology Venereology & Leprology, Nepalgunj Medical College Teaching Hospital Kohalpur, between May 2017 to October 2018. Before initiating the study the proposal of the study was submitted to the Institutional Review Board. The study population included the patients

visiting the OPD of Department of Dermatology, Venereology and Leprology of NGMCTH who were diagnosed as having psoriasis either on the clinical ground and/or histopathologically.

**Inclusion criteria included**

**Case:**
- a) Clinically and/or histopathologically diagnosed cases of psoriasis by a dermatology consultant.
- b) Age > 16 years, belonging to either gender.

**Control**
- a) Age and sex matched healthy adult population who were hospital staff or attendants of the patients.
- b) More than 16 years age, belonging to either gender.
- c) No evidence of psoriasis or any other systemic illness.

Altogether 112 (both case and control) patients were included in the study. Diagnosis of psoriasis was made clinically by the consultant dermatologist. The PASI score, BMI were calculated by the author himself. The will of the subjects was fully respected and those who did not give consent for participation were excluded from the study. A written consent was taken from each patient after explaining the relevant details of the study, its importance and implications. Confidentiality was maintained to utmost. Detailed history was taken and detailed clinical examination and investigation was performed and the details were recorded. Statistical analysis was done using SPSS 20. Fisher’s exact test was used for significance testing and P value less than 0.05 was considered significant. Odds ratio was used to compare the risk between cases and controls.

**RESULTS**

A total of 56 cases were included in the study. Fifty six age and sex matched controls were also enrolled. Age of the cases ranged from 18 to 82 years with the mean age 41.68 ± 19.04 years. Age of the controls ranged from 19 to 92 years with mean age 39.46 ± 16.27 years. There was no significant difference in age distribution of cases and controls across the groups (P value = 0.796) as shown in figure 1.

**Gender distribution**

Out of 56 cases, 26 (46.6%) were male and 30 (53.6%) were female. Out of 56 controls, 25 (44.6) were male and 31 (55.4%) were female as shown in figure 2. There was no significant difference in proportion of male and female between cases and controls (P value = 1).

**Severity of the disease (PASI)**

PASI score ranged from 4.4 to 28.2 with mean PASI score 11.02 ± 5.4.

**BMI (in kg/m²)**

BMI in cases ranged from 16.7 to 34.2 with mean 24.3±4.3 and in controls it ranged from 15.5 to 29.1 with mean 21.9±3. Mean BMI was significantly higher in cases than controls with p value = 0.001 shown in table II.
had 2.8 times increased odds of getting high BMI than controls. Prevalence of BMI in table V.

In this study, Duration of disease ranged from 2 months to 360 months with mean duration of 72.21 ± 67.23 months which was similar to study done by Lakshmi et al11, Madanagobalane et al12 and Gisondi et al13. In this study PASI score ranged from 4.4 to 28.2 with mean PASI score 11.02±5.4 which is similar to study done by Lakshmi et al11 Madanagobalane et al12.

There was no significant difference in the mean disease duration between the groups having BMI ≥ 25 kg/m² and BMI <25 kg/m². Similar results were seen in study done by Mallbris et al14 and Nisa et al15. However, the study done by Mallbris et al14 and Nisa et al15 had shown positive association between disease duration and BMI.

**CONCLUSION**

Psoriasis is one of the chronic inflammatory skin diseases, affecting mostly young adults. Different studies have shown its is association with higher prevalence of metabolic syndrome. This study also supports the finding of significantly higher prevalence of obesity in psoriatic patients than control group. Thus, psoriasis should not be regarded as a simple skin disease but rather as a systemic inflammatory disease. The knowledge that psoriasis can be associated with obesity can make dermatologist to screen the psoriatic patient early for obesity and patients can be advised about adapting healthy lifestyle, including diet and exercise.

**Limitation of the study**

The sample size was small to draw the valid inferences to the larger population

**DISCUSSION**

There have been many studies linking psoriasis to the individual components of the metabolic syndrome since many years. A total of 56 cases and age and sex matched 56 controls were enrolled in this study. Age of the psoriatic patients ranged from 18 to 82 years with mean age 41.68 ±19.04 years and maximum number of patients were of age group 16 to 35 years, which was similar to the study done at TUTH by Shrestha et al16. There were slightly higher proportions of female (53.6 %) than male (46.6%) in this study but the study done by Shrestha et al16 showed slightly higher proportion of male (51.7%) than female (48.3%) however the difference was not statistically significant.

In this study, Duration of disease ranged from 2 months to 360 months with mean duration of 72.21 ± 67.23 months which was similar to study done by Lakshmi et al11, Madanagobalane et al12 and Gisondi et al13. In this study PASI score ranged from 4.4 to 28.2 with mean PASI score 11.02±5.4 which is similar to study done by Lakshmi et al11 Madanagobalane et al12.

There was no significant difference in the mean disease duration between the groups having BMI ≥ 25 kg/m² and BMI <25 kg/m². Similar results were seen in study done by Mallbris et al14 and Nisa et al15. However, the study done by Mallbris et al14 and Nisa et al15 had shown positive association between disease duration and BMI.
