Anemia among Pregnant Women at Nepalgunj Medical College

BC D

ABSTRACT

Introduction: Anemia in pregnancy is major health issue of developing countries responsible for adverse maternal and fetal outcome. According to World health organization pregnant women with hemoglobin level less than 11 gm/dl in first trimester and less than 10.5gm/dl in second and third trimester are considered to be anemic. Iron deficiency anemia is common during pregnancy followed by megaloblastic anemia. Aims: To find out the prevalence of anemia during pregnancy. To correlate the maternal and fetal complications associated with anemia during pregnancy. Methods: This is a prospective hospital based study done at department of obstetrics and gynecology Nepalgunj Medical College from July 2020 to January 2021. All pregnant women with hemoglobin level <11 gm/dl were enrolled in the study. Data were collected from antenatal clinic and biochemistry laboratory. Results: In this study maximum participants were of age group 20-25 consisting of 38.5%. Anemia was more common in multiparous i.e. 60% as compared to primipara i.e. 40%. In this study maximum participant had vaginal delivery (57%) followed by LSCS (29%) then instrumental delivery (14%). These ladies had complications like postpartum hemorrhage (27.7%), preterm labor (16.9%), pregnancy induced hypertension (9.2%). similarly 10.8% had sepsis and 20% had no complications. About 23.1% babies delivered by anemic ladies required neonatal intensive care. Intrauterine growth restriction was seen in 12.3%, preterm birth in 10.3% and 53.8% babies had no complications. Conclusion: The prevalence of anemia during pregnancy is high leading to adverse maternal and fetal outcome.

INTRODUCTION

Anemia in pregnancy is a major health issue of developing country, responsible for adverse maternal and fetal outcome. It is decrease amount of red blood cell or hemoglobin (Hb) concentration with decrease oxygen carrying capacity of blood during pregnancy. According to WHO pregnant woman with hemoglobin level less than 11 gm/dl in first trimester and less than 10.5gm/dl in second and third trimester are considered anemic and divided in to mild anemia (Hb 9 to 10.0gm/ dl) moderate anemia (Hb 7 to 8.9 gm/dl) severe anemia hemoglobin less than 7gm/dl. The most common cause of anemia during pregnancy is iron deficiency anemia, other causes like folate, vitamin B12 deficiency; congenital anemia (Sickle anemia, Thalassemia) may worsen during pregnancy due to increase demands.

Hemolytic anemia, aplastic anemia and hematologic malignancies are less common cause of anemia during pregnancy. There is a risk of intra uterine fetal death, preterm labor, neuro developmental damage to fetus and risk of heart failure, eclampsia, pre-eclampsia post-partum hemorrhage, maternal mortality, risk of blood transfusion and operative delivery. Anemia in pregnancy is common in this region also hence the study was carried out to evaluate the prevalence, types and severity of anemia and to correlate the association between the anemia and maternal and fetal complications.

METHODS

This was a prospective hospital based study done at Department of Obstetrics and Gynecology Nepalgunj Medical College. Data were collected from July 2020 to January 2021. Ethical clearance was taken from institutional review committee. All pregnant women who attended antenatal clinic with hemoglobin level less than 11gm/dl were enrolled in the study. The pregnant ladies with chronic illness were excluded from the study. The informed and verbal consent was taken; data were collected on the basis of age group, types of anemia, maternal complications and fetal complications. Data were recorded in standard Performa and analyzed by using version 17 of SPSS.

RESULTS

During the study period 2500 pregnant ladies visited antenatal

study conducted by Diejomaoh F.M.E. where the incidence of iron deficiency anemia was 58%. In our study 27.7% had post-partum hemorrhage (PPH), 16.9% had preterm labor. The study conducted by Maskey M. PPH was seen in 92.9% and 1% had preterm labor. In the study conducted by Patra S., 57% of babies required NICU admission, 90% had preterm birth, 30% were low birth weight/ intrauterine growth restriction (IUGR). In our study 23.1% had NICU admission only 10.3% had preterm birth and 12.3% babies had IUGR.

LIMITATIONS

Limitations of this study are small sample size and short duration of study. Because of the diversified cultural practices food habits in different ethnic groups cause and prevalence of anemia during pregnancy is different so studies should be done separately for different ethnic groups.

CONCLUSION

Anemia during pregnancy is responsible cause for adverse fetomaternal outcome like postpartum hemorrhage ,prenancy induced hypertension ,preterm labor in mother and risk of preterm birth ,NICU admission, IUGR ,Low birth weight in newborn. Hemoglobin level below 10.5 gm/dl in any trimester should be screened to rule out cause of anemia. During pregnancy proper diagnosis and treatment of anemia is required to prevent complication.
