THE PREVALENCE OF INTESTINAL PARASITIC INFESTATION IN A TERTIARY CARE HOSPITAL-A RETROSPECTIVE STUDY

Ganesh Kumar Singh, Kamal Prasad Parajuli, Medhavi Shrestha, Santwana Pandey, Shekhar Chandra Yadav

Abstract:

Intestinal parasitosis is highly prevalent among the general population in Nepal. This study aimed to evaluate the distribution of intestinal parasites among patients attending Nobel Medical College Teaching Hospital, Biratnagar, Nepal. A total of 5,524 stool samples examined by direct smear and Formal-Ether concentration technique were reported.

The overall prevalence of intestinal parasitic infection was found to be 15.17% (M=15.65% vs F=14.62%). The overall prevalence of intestinal parasitosis was found to be highest among patients aged 5-14 years (20.66%), followed by elderly people aged > 45 years (16.20%) and least among children aged < 5 years (9.09%). Among various parasites detected, the most common was Entamoeba histolytica (44.86%) followed by Giardia lamblia (33.65%), hookworm (10.50%), Ascaris lumbricoides (5.72%), Strongyloides stercoralis (4.77%), Hymenolepis nana (3.34%), Trichuris trichiura (0.95%) and Enterobius vermicularis (0.23%) respectively.

Keywords: Intestinal parasites; Prevalence; Stool; Infection.

Introduction

It is estimated that some 3.5 billion people are affected, and that 450 million are ill as a result of Intestinal parasites and protozoan infections worldwide, the majority being children, as they cause iron deficiency anemia, growth retardation in children and other physical and mental health problems.1,2 The prevalence rates of enteric parasitosis reported from Nepal vary from considerably low to nearly one hundred percent7,8,9 This variation is probably due to difference in time, place and method used.

The developing countries are more prone to intestinal and extra-intestinal parasitic diseases causing important public health problems.3 Transmission of intestinal parasites is associated with poor personal hygiene which also encourages person to person transmission, poor food hygiene and the presence of flies as well as contaminated drinking water.4 In Nepal about 70% of health problems is due to infectious diseases and diarrheal disease alone is one of the major cause of morbidity and mortality.5,6 The prevalence rates of enteric parasitosis reported from Nepal vary from considerably low to nearly one hundred percent7,8,9 This variation is probably due to difference in time, place and method used.

There is insufficiency of epidemiological data on the diffusion and prevalence of intestinal parasites in symptomatic patients. The microbiology laboratory of our hospital is receiving an increased number of requests for the analysis of stool specimens for ova and parasites. This trend prompted us to evaluate the distribution of intestinal parasites isolated by our laboratory over a two years period. Authors believe that these studies are important
as they provide basic data for the control of parasitic infection in future.

Material and methods

A total of 5,524 samples (Male=2912 and Female=2612) from the outpatient as well as inpatient departments during the period of two years from 1st January 2010 to 31 December 2011 received at the department of microbiology, central laboratory, Nobel Medical College Teaching Hospital, Biratnagar, Nepal were included in the current study. Subjects were divided into age groups (<5, 5-14, 15-24, 25-44, >45 yrs), and gender (Male/female).

The patients were provided wide mouthed clean, dry, properly labeled plastic container for collection of samples and recommend 5grams of solid or 10ml of liquid stool. The stool samples were examined within 1-2 hours of collection. Macroscopic examination was done to look for structures like proglottids, scolices, adult tapeworm, *Enterobius, Ascaris, Trichuris* or hookworm. Unstained saline wet mount preparation was done to detect protozoal tropozoites and helminthic eggs or larvae. Iodine wet mount was done to detect cysts. The Formal-Ether concentration technique was performed for those cases which were negative by saline preparation method but had strong clinical suspicion of intestinal parasitism. The findings of stool examination were subjected to analysis by using SPSS version 16.

Comparatively parasitic infection was found to be almost equal among males and females (456/2912 vs 382/2612) The overall prevalence of intestinal parasitosis was found to be highest among patients aged 5-14 years (20.66%), followed by elderly people aged > 45 years (16.20%) and least among children aged < 5 years (9.09%) (Table-1).

Among various parasites detected, the most common was *Entamoeba histolytica*, (44.86%) followed by Giardia lamblia (33.65%), hookworm (10.50%), *Ascaris lumbricoides* (5.72%), *Strongyloides stercoralis* (4.77%), *Hymenolepis nana* (3.34%), *Trichuris trichiura* (0.95%) and *Enterobius vermicularis* (0.23%) respectively (Figure-2).
The prevalence of intestinal parasites stratified by age groups is shown in Figure 3. Statistically significant differences in the frequency of *E. histolytica*, *G. lamblia* and *H. nana* was observed according to age with highest prevalence of *E. histolytica* in age group 25-45 years and *G. lamblia* and *H. nana* in age group 5-14 years. The distribution of intestinal parasites stratified by age groups revealed increase in soil transmitted helminthes (*S. stercoralis* and Hookworm) with age (*p*<0.05). There was no statistically significant difference in the percentage of *A. lumbricoides*, *T. trichura* and *E. vermicularis* according to the age of the patients (*p*>0.05).

**Discussion:**

The prevalence of intestinal parasitoses found in our study is much lower than that reported earlier from elsewhere in Nepal, but still it seems alarmingly high in comparison to international scenario. This variation is probably due to difference in time, place, method used, health awareness, and living standards.

Gender wise prevalence of parasitic infection was observed almost equal among males and
females, though slightly higher in males (15.65% vs 14.62%) which shows agreement with reports from Nepal and other countries regarding gender independence of parasitic infection.\textsuperscript{13,14,19-23}

Based on the age, prevalence of parasitic infection was highest among patients aged 5-14 years (20.66%) followed by > 45 years (16.20%). This finding is similar to the studies done in different parts of Nepal.\textsuperscript{19,20} In contrast it was lowest among children aged <5 years (9.09%) in our study. High parasitic infection found among school aged children might be due to their unhygienic behavior and lack of sanitation.

The higher infection with E. histolytica may be attributed to poor sewerage system in the community, and the fecal contamination of ground water, the ground water being major source of drinking water in the region. Similarly, higher helminthic infection, particularly by Hookworm and Ascaris, in this study suggests high soil contamination with infective stage of helminths. This report seems similar to that of another study and might be due to rapid, unplanned urbanization, open defecation and other unhygienic conditions and lack of health awareness.\textsuperscript{19} Hookworm infection detected among more than one tenth population in this study might be related to poor farmers residing in the locality who usually work bare foot in the farm, which might have been contaminated with infective stage of hookworm.

Though, the overall prevalence of intestinal parasitosis among the hospital visiting patients is declining, the high detection of parasites like E. histolytica, G. lamblia, Hookworm, S. strongyloides and A. lumbricoides signifies the need of public awareness regarding use of latrine, water source protection from fecal contamination, proper sanitation and hygienic behavior along with the continuity to the mass deworming program.
