INTRODUCTION
Ectopic pregnancy is the implantation of a fertilized ovum outside the endometrial cavity. It occurs in approximately 0.5–2% of pregnancies and is potentially life threatening. The possible causes of increase in incidence of ectopic pregnancy are pelvic inflammatory disease, use of intrauterine contraceptive device, tubal surgical procedures, induced abortion followed by infection, increasing age, smoking, etc. Diagnosis requires a high index of suspicion as the classic triad of amenorrhea, abdominal pain and vaginal bleeding is not seen in majority of cases. Women may present with non-specific symptoms, unaware of an ongoing pregnancy or even present with hemodynamic shock. Other symptoms like nausea, pain lower abdomen, shoulder pain may also be present. The 95% of ectopic pregnancies occur in fallopian tube and out of which 55% occur in ampulla, isthmus (20–25%), fimbriae (17%) and interstitial segment (2–4%). Other sites of ectopic pregnancy are ovarian (0.5–1%), cervical (0.1%) and abdominal pregnancy (0.03%). The diagnosis of ectopic pregnancy can be difficult. Measurement of serum progesterone, serial serum beta-human chorionic gonadotrophin (β-hCG) levels, transvaginal ultrasonography (TVS) and laparoscopy are the diagnostic tools. Early diagnosis and prompt treatment is associated with better outcome. Treatment options for ectopic pregnancy include medical therapy (methotrexate) and surgery (open or laparoscopic). Management depends on individual basis. The purpose of this study was to analyze the patients with ectopic pregnancy.

METHODS
This was a retrospective medical record review at Paropakar Maternity and Women’s Hospital (PMWH) in Kathmandu. Ethical approval was taken from the hospi-
tal Institutional Review Committee. The medical records of ectopic pregnancy were reviewed from 15 January to 15 July 2020. Data pertaining patient characteristics, age, gravida, risk factors, clinical presentation, diagnostic modality, site of ectopic pregnancy, management and morbidity associated with it were retrieved and descriptive analysis done using SPSS version 16.0.

RESULTS
There were 88 ectopic pregnancies out of 10123 deliveries (0.86%) in six months and 18 (20.5%) cases were referred-in from different hospitals. Fourteen cases (15.9%) did not have history of amenorrhoea. [Table-1]

Majority of the cases were surgically managed (87; 98.9%) and the most commonly performed surgical procedure was salpingectomy (81.8%). One case underwent left cornual wedge resection with left salpingectomy and right tubal ligation in 43 years, G3P3+1 with previous LSCS, ultrasonography (USG) revealed ectopic pregnancy. Patient underwent laparotomy and had left ruptured cornual ectopic pregnancy with hemoperitoneum 500 ml. Two units blood transfused and discharged on 3rd POD. One case had medical management with single dose of Methotrexate (MTX) 50 mg intra-muscularly. She was 32 years, G2P1, previous lower segment cesarean section (LSCS) with secondary subfertility and in-vitro-fertilization (IVF) conception who did not have amenorrhoea, presented with pain abdomen and per vaginal (P/V) bleeding for 15 days. Her serum β-hCG was 392 mIU/ml and TVS revealed (18x17 mm) left adnexa ectopic pregnancy without cardiac activity. [Table- 4]

Regarding morbidity associated with ectopic pregnancy 36 (40.9%) had blood transfusion and 11 (12.5%) required general anesthesia (GA). Patients requiring to stay hospital for more than 7 days (15.9%) were because previously they were diagnosed as threatened abortion (1/14), complete abortion (2/14), adnexal cyst (1/14) and pregnancy of unknown location (PUL) (4/14); after 4 to 6 days, following serial β-hCG and USG, underwent laparotomy for ectopic pregnancy. One case (1/14) was medically managed and another (1/14) had bowel serosa injury repair. Four (4/14) had ruptured ectopic pregnancy with blood loss ranging from 1500 to 3000 ml requiring four to six units of blood transfusion. There was no maternal mortality.

**DISCUSSION**

The incidence of ectopic pregnancy was 0.86% which was similar to a study by Yadav A et al.\(^ \text{13} \) (0.89%) whereas slightly higher incidence was seen in other studies 1.3%,\(^ \text{14} \) 1.4%,\(^ \text{15} \) 1.8%\(^ \text{16} \) and 1.9%\(^ \text{17} \).

The majority of ectopic pregnancy cases occurred in 30 to 34 years age group (28.4%) which was similar to a study by Kaveri et al.\(^ \text{19} \) (31 to 35 years). However, other studies\(^ \text{17-19} \) found more of these cases in 20 to 30 years age group. In this study, more of ectopic pregnancy was seen in multiparous (65%) which is similar to various other studies.\(^ \text{13,16,17,19,20} \)

Amongst the risk factors studied, history of having previous abortion was the most common finding (25%). Similar observations were seen by Rajita et al.\(^ \text{13} \)\(^ \text{17} \), Shraddha et al \(^ \text{13} \)\(^ \text{17} \), Arati et al \(^ \text{13} \)\(^ \text{17} \) and Ansa et al \(^ \text{13} \)\(^ \text{17} \). This could be due to infection following abortion causing tubal damage or dysfunction. In this study, use of medical abortion was 7.9% which is comparable to a study by Shradhha et al (9.7%).\(^ \text{21} \)

The self medication of abortifacient without supervision increases the chances of missing the ectopic pregnancy. The overall risk of developing ectopic pregnancy by over the counter abortifacient is as high up to 1.9% to 6.5%.\(^ \text{24,25} \) In this study, another risk factor, previous ectopic pregnancy was 4.5% which is similar to studies by Ansa et al (4.4%),\(^ \text{26} \) Hussam et al (4.7%),\(^ \text{27} \) Shraddha et al (3.2%)\(^ \text{21} \), Anita et al (5.4%)\(^ \text{13} \) and Rajendra et al (5.7%).\(^ \text{17} \)

This is most likely due to tubal factors that are usually bilateral. In this study, bilateral tubal ligation and previous LSCS were 4.5% and 14.8% respectively which is comparable to studies by Mridula et al (6.4%, 12.8%),\(^ \text{19} \) Shanti et al (12.9%, 6.4%)\(^ \text{20} \), Anita et al (10.9%, 26.02%)\(^ \text{13} \) and Bhawana et al (7.9%, 2.6%)\(^ \text{15} \). Similarly, Nitesh et al\(^ \text{19} \) had previous LSCS in 11.5% of their patients. In this study, subfertility was seen in 4.5% (1.1% IVF conception) which is similar to studies by Shanti et al (4.8%),\(^ \text{20} \) Shraddha et al (3.2%)\(^ \text{21} \) and Anita et al (2.7%)\(^ \text{13} \), in contrary, it was higher in various other studies Tahmina et al (18.8%),\(^ \text{8} \) Rajita et al (18%)\(^ \text{8} \) and Ansa et al (22.2%).\(^ \text{26} \) In this study, use of oral contraceptive pills (OCP) and emergency contraceptive pills were 2.3% and 1.1% respectively. Use of OCP was seen in studies by Shanti et al (1.6%)\(^ \text{20} \) and Rajendra et al (7.6%)\(^ \text{17} \) whereas use of emergency contraceptive pill was higher in a study by Kaveri et al (36.3%).\(^ \text{16} \) Also in this study, 1.1% had history of tuberculosis which was slightly higher in other studies 3.8%\(^ \text{17} \) and 8.5%.\(^ \text{19} \)

The presentation of ectopic pregnancy is variable. In this study, the most common presenting symptom was abdominal pain (71.6%) followed by vaginal bleeding (60.2%) and amenorrhoea (56.8%) which is similar to the studies by Archana et al (100%, 95%, 86.2%)\(^ \text{22} \) and Smita et al (96%, 52%, 48%).\(^ \text{28} \) However, in this study, amenorrhoea was absent in 15.9% of the patients. In the absence of amenorrhoea, woman may be unaware of an ongoing pregnancy and hence may not anticipate a pregnancy associated complication. This subjects her to increased risk due to delayed diagnosis. The classic triad of amenorrhoea, pain abdomen and vaginal bleeding was seen in 15.9% which is in contrast to other studies by Rajendra et al (53.8%),\(^ \text{17} \) Archana et al (71%)\(^ \text{22} \) and Smita et al (60%).\(^ \text{28} \) Two cases (2.3%) presented to hospital in hypovolemic shock while more cases of shock were seen in various other studies by Tahmina et al (26.4%)\(^ \text{4} \), Smita et al (32%),\(^ \text{28} \) Archana et al (42.5%)\(^ \text{22} \) and Rajendra et al (51.9%)\(^ \text{17} \). In this study, clinical signs of abdominal tenderness and cervical motion tenderness were seen in 61.4% and 51.1% respectively which is comparable to a study by Tahmina et al (75%, 58.3%).\(^ \text{4} \) Hence, in this study, 47.7% cases could be diagnosed by clinical alone. Diagnosis of ectopic pregnancy can be challenging because presentation can vary significantly. Although clinical examination may raise the suspicion of an ectopic pregnancy, relying on clinical signs and symptoms alone would have missed the diagnosis in 13.6% of the cases in this study. USG was useful in diagnosing most of these cases along with clinical and serial serum β-hCG.
In this study, ectopic pregnancy occurred in fallopian tubes, ampulla (71.6%) being the most common site followed by isthmus (6.8%), fimbria (2.3%) and cornua (1.1%) which is similar to other studies. Similarly, ampullary part of the tube was commonly involved in most of the ectopic pregnancies in various other studies. The right side was more frequent than the left which was consistent with different other studies. Our hospital being a tertiary level referral centre, 60.2% of the women had ruptured ectopic pregnancies which is comparable to most of the studies ranging from 56% to 91.5%. Since most of the patients had ruptured ectopic pregnancy, they required emergency laparotomy and salpingectomy (81.8%) as life saving measures. Moreover, 13.6% had chronic ectopic with adnexal adhesion necessitating salpingectomy. Most other studies also underwent salpingectomy as the primary surgery and ranged from 58% to 96.8%. In this study, hemodynamic instability was the major factor of morbidity necessitating blood transfusion. In a study by Shanti et al.,4 mean duration of hospital stay was 6.6 ± 2.9 days. Other studies reported >10 days (21.1%),17 ≥8 days (12.5%)4 and >8 days (5.6%).30 In our hospital a study by Tahmina et al,4 reported 3.2% maternal mortality in their study. Fortunately, there was no maternal mortality due to ectopic pregnancy in this study as in majority of other studies.5,6,13,17,19,21,22 This may be as a result of prompt and proper management of patients after reporting to the hospital pertaining to improved diagnostic and treatment modalities.

CONCLUSIONS

Majority of the patients had ruptured tubal ectopic pregnancy. Most of them required surgical management, salpingectomy being the most common. The most common morbidity associated was hemodynamic instability requiring blood transfusion. There was no maternal mortality.
