ABSTRACT
This paper reports the variation of atmospheric transmittance with meteorological parameters over Jumla (Lat. 29.28° N, Long.: 82.16° E and Alt.: 2300 m above sea level) from 2011 to 2013 (three years) by using CMP6 pyranometer and satellite data. The trends of monthly and seasonal variations of atmospheric transmittance, solar insolation and clearness index have been analyzed. The result exemplifies that during the study period, average value of global solar radiation, solar insolation and clearness index are 19.26 ±3.88 MJ/m²/day, 4.95±1.14 kWh/m²/day and 0.59 ±0.12 respectively. The average value of atmospheric transmittance during the whole study period is 0.60 ± 0.11. The average value of atmospheric transmittance of ozone, Rayleigh scattering, gas mixture, water vapor and aerosol are 0.9830±0.0007, 0.8999±0.0178, 0.9875±0.0007, 0.8839±0.0101 and 0.7836±0.0909 respectively. There is positive correlation of relative sunshine hour and negative correlation of rain fall with atmospheric transmittance. Result of this research work is beneficial for the further analysis of solar radiation at different places improving life of flora and fauna and protecting the whole environment.

Keywords: Clearness index, Global solar radiation, Meteorological parameters, Solar insolation

1. INTRODUCTION
The Sun is the closest star from The Earth. The main source of energy of the Sun is thermonuclear fusion reaction. Four hydrogen nucleus combine and form helium nucleus on emission 26.7 MeV energy in form of electromagnetic wave of wave length range 0.3 μm to 3 μm (Poudyal et al. 2011). The Sun radiates 4 × 1026 J energy per second (Wallace & Hobbs 2006). Average solar radiation
1367W/m² (solar constant, Isc) (Duffie & Beckman 2013) incidents on outer layer of the atmosphere when the Earth is at mean distance 1.49×108km from the Sun. As orbit of the Earth around the Sun is elliptical, the solar energy incident on specific point of outer atmosphere (Ho) is inversely proportional to square of distance between the Sun and the Earth at specific time. The solar energy passing through the atmosphere is scattered and absorbed by molecules and particles. The solar energy interacts with large particle of the atmosphere such as water droplets, dust and aerosol. By Beer Lambert’s law, solar radiation decreases exponentially with extinction coefficient (k) and optical air mass(m) in the atmosphere, the solar radiation on ground(Hg) is given by(Iqbal 1983;Liou 2002)

\[ H_g = H_o e^{-km} \]

Ratio of Hg to Ho is atmospheric transmittance (\( \tau \)) or clearness index (\( K_r \)).

The solar energy is the fundamental as well as primary source of energy for the Earth. Study of atmospheric transmittance and its effect of different meteorological parameters are used in different area: Agriculture, Hydrology, Climate change and so on. The solar radiation on ground depends on different physical parameters (latitude, longitude, altitude, aerosol, cloud, absorption, ozone and albedo) and meteorological parameters (precipitation, ambient temperature, wind speed, humidity, local weather conditions and seasonal variation).

Nepal is a land-locked South East Asian mountainous country with area of beautiful landscape situated between latitudes of 26.36ºN to 30.45ºN and longitudes of 80.06ºE to 88.2ºE. The elevation of the country ranges from 60m to 8848m within a span of less than 200 km from south to north and about 800km from east to west (Majupuria 1999). In fiscal year 2010/2011, 425TJ energy is consumed in Nepal (MoF 2010/011). Out of that energy, tradition fuel is 83.7 percentages, commercial fuel is 15.5 percentages and renewable energy is 0.8 percentage. Large amount of petroleum oil are used in vehicle and domestic fuel. Combustion of petroleum oil produces air pollution. Nepal is situated between two big industrial countries India and China and their industrial byproduct can directly affect the atmosphere above Nepal. Therefore, detail study of atmospheric transmittance is very important.

Jumla (Lat.:29.28º N, Long.: 82.16º E and Alt.: 2300 m a.s.l.) situates in Himalayan mountainous region in the Mid-Western region of Nepal, covers area 2,531 sq. km is shown in Fig.1.Population and population density are 108,921 and 43 per sq.km respectively (CBS 2011). Rara Lake, largest of lake of Nepal lies in this region at an altitude of 2,990 m above sea level. t lies in alpine climatic zone (Adhikari et al. 2013). The annual average measured value of global solar radiation(GSR) is 19.90±0.66 MJ/m²/day in Jumla for 2011 (KC et al. 2016).

2. MATERIALS AND METHODS

Extinction of solar radiation (k) is sum of extinction due to gas mixture, water vapor, ozone, aerosol and Rayleigh scattering. So atmospheric transmittance is transmittance due to ozone(\( \tau_{oz} \)), water vapor (\( \tau_w \)), gas mixture (\( \tau_g \)), aerosols (\( \tau_a \)) and Rayleigh scattering (\( \tau_r \)) (Iqbal 1983).

\[ \tau = \tau_{oz}\tau_w\tau_g\tau_a\tau_r \]

\( \tau_{oz} \) depends on ozone column (l) and relative air mass (m_r). Relative air mass depends on zenith angle (\( \theta_z \)), \( \tau_w \) depends on water content (w) and relative air mass. Water content relates
relative humidity (RH) and air temperature T). \( \tau_g \) and \( \tau_r \) depend on air mass \( (m_r) \) which depends on atmospheric pressure \( (P) \), altitude and relative air mass. \( \tau_a \) depends on Angstrom turbidity coefficient \( (\beta) \), Angstrom exponential \( (\alpha) \) and air mass.

\[
\tau_{oz} = 1 \left[ 0.1611 u_3 \left(1 + 139.48 u_3 \right)^{-0.3035} \right] \cdot 0.002715 u_3 \left(1 + 0.044 u_3 + 0.0003 u_3^2 \right)^{-1}
\]

\[
\tau_w = 1 - 2.4959 w m_r \left(1 + 79.034 w m_r \right)^{0.682} + 6.385 w m_r \right]^{-1}
\]

\[
\tau_g = e^{-0.0127 m_a^{0.26}}
\]

\[
\tau_a = \left(0.1244 \alpha + 0.0162\right) + \left(1.003 \cdot 0.125 \alpha \right) e^{-\beta m_a \left(1 + 0.089 \alpha + 0.5123\right)}
\]

\[
\tau_r = e^{-0.0903 m_a^{0.83} \left[1.01 + m_a \cdot m_a^{1.01}\right]}
\]

\[
u_3 = l m_r
\]

\[
m_a = \frac{P}{101325}
\]

\[
m_r = \frac{1}{\cos \theta_z + 0.15 \left(93.885 \theta_z \right)^{-1.253}}
\]

\[
w = 0.493 \left(\frac{RH}{T}\right) e^{26.23 \left(\frac{5416}{T}\right)}
\]

The Global solar radiation (GSR) is the sum of direct solar radiation and diffused solar radiation. Daily GSR and meteorological data are collected from Department of Hydrology and Meteorology (DHM), Government of Nepal for three years 2011, 2012 and 2013 for Jumla. First class CMP6 pyranometer is used by DHM to measured GSR in W/m². It has thermopile sensor with spectral range of 285nm to 2800nm as shown in fig.2 (Kipp and Zonen 2008). Total ozone column data are collected from website http://data.ceda.ac.uk/badc/toms/data/omi/. Clearness index and solar insolation data are collected from website https://power.larc.nasa.gov/data-access-viewer/.

Fig.2: CMP6 pyranometer [source: www.kippzonen.com]
MATLAB 2015 software is used to analysis data and open source software Python 3.7 is used to plot graph. Mean ($\bar{x}$), standard deviation ($\sigma$), correlation coefficient ($r$) are used as statistical tool. Standard error (SE) is used as error bar in graph. Data is presented in form mean ± standard deviation.

$$\sigma = \sqrt{\frac{n}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2}$$

$$SE = \frac{\sigma}{\sqrt{n}}$$

$$r = \frac{\sum_{i=1}^{n} (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n} (x_i - \bar{x})^2 \sum_{i=1}^{n} (y_i - \bar{y})^2}}$$

### 3. RESULTS AND DISCUSSION

Monthly variation of GSR is shown in Fig.3(a). The maximum and the minimum values of GSR are 20.44±4.47 MJ/m$^2$/day in September and 13.90±2.03 MJ/m$^2$/day in December respectively. Variation is large in July and less in October. Fig.3(b) shows monthly variation of solar insolation. The maximum and the minimum values of solar insolation are 6.31±1.37 kWh/m$^2$/day in April and 3.93±0.61 kWh/m$^2$/day in December respectively due to solar declination. Variation is large in June and less in November. Fig.3(c) shows monthly variation of clearness index. The maximum and the minimum values of clearness index are 0.66±0.09 in October and 0.40±0.09 in July respectively due to local weather and aerosols. Variation is large in February and less in November. Fig.3(d) shows monthly variation of atmospheric transmittance. The maximum and the minimum values of transmittance are 0.70±0.06 in November and 0.44±0.12 in July respectively. Variation is seen to be large in February due to solar declination and less in October due to day length.

Fig. 3: Monthly variation of parameters (GSR, solar insolation, clearness index, atmospheric transmittance)
Fig. 4(a) shows seasonal variation of GSR. The maximum and minimum values of GSR are 22.92 ±4.04 MJ/m²/day in spring and 14.99±3.57 MJ/m²/day in winter respectively. GSR varies large in summer whereas less in in winter. Fig. 4(b) shows seasonal variation of solar insolation. The maximum and the minimum value of solar insolation are 6.26±1.35 kWh/m²/day in spring and 4.06±1.13 kWh/m²/day in winter respectively. Solar insolation varies large in spring and less in autumn.Fig. 4(c) shows seasonal variation of clearness index. The maximum and minimum values of clearness index are 0.64±0.13 in spring and 0.45±0.09 in summer respectively. Clearness index varies large in winter and less in autumn. Fig. 4(d) shows seasonal variation of atmospheric transmittance. The maximum and the minimum values of transmittance are 0.66±0.09 in autumn and 0.48±0.11 in summer respectively. Variation of transmittance is large in summer due to large day length and less in autumn due to solar declination.

Fig. 5(a) shows monthly variation of transmittance due to ozone($\tau_{oz}$). The maximum and the minimum value of $\tau_{oz}$ are 0.9862 in May and 0.9781 in December respectively due to TOC. Fig. 5(b) shows monthly variation of transmittance due to gas mixture($\tau_g$). The maximum and the minimum value of $\tau_g$ are 0.9883 in June and 0.9863 in December respectively due to optical air mass. Fig. 5(c) shows monthly variation of transmittance due to Rayleigh scattering($\tau_r$). The maximum and the minimum value of $\tau_r$ is 0.9185 in June and 0.8690 in December respectively due to air mass. Fig. 5(d) shows monthly variation of transmittance due to water vapor($\tau_w$). The maximum and minimum value of $\tau_w$ are 0.8953 in March and 0.8694 in August respectively due to water content. Fig. 5(e) shows monthly variation of transmittance due to aerosol($\tau_a$). The maximum and the minimum value of $\tau_a$ are 0.9376 in November and 0.5855 in July respectively due to aerosols.
Fig. 5: Monthly variation of various atmospheric transmittances due to ozone, gas mixture, Rayleigh Scattering, water vapor and aerosol.

Fig. 6(a) shows variation of atmospheric transmittance with the maximum temperature. Correlation coefficient is -0.61. Fig. 6(b) shows variation of atmospheric transmittance with the minimum temperature. Correlation coefficient is -0.83. Fig. 6(c) shows variation of atmospheric transmittance with relative humidity. Correlation coefficient is -0.83. Fig. 6(d) shows variation of atmospheric transmittance with rainfall. Correlation coefficient is -0.85. Fig. 6(e) shows variation of atmospheric transmittance with water content. Correlation coefficient is -0.85. Fig. 6(f) shows variation of atmospheric transmittance with relative sunshine hour (n/N). Correlation coefficient is 0.98. Here n is sunshine hour and N is day length. Fig. 6(g) shows variation of atmospheric transmittance with total ozone column (TOC). Correlation coefficient is 0.32. There is a positive relation of transmittance with relative sunshine hour whereas other parameters have a negative relation.
4. CONCLUSION

During the study period of 2011 to 2013 in Jumla, annual value on of GSR, solar insolation and clearness index(KT) are 19.26±3.88 MJ/m²/day, 4.95 ±1.14 kWh/m²/day and 0.59±0.12 respectively. Annual average of atmospheric transmittance (τ) is 0.60±0.11. This shows that in Jumla about 60% of solar radiation is transmitted through the atmosphere. Annual mean of atmospheric transmittance due to gas (τg), ozone(τo), Rayleigh scattering (τr), water vapor (τw) and aerosols (τa) are 0.9875±0.0007, 0.9830±0.0007, 0.8999 ±0.0178, 0.8839±0.0101 and 0.7836±0.0909 respectively. There is positive correlation of atmospheric transmittance with relative of sunshine hour and negative correlation with rain fall. The yearly mean of atmospheric transmittance due to Rayleigh scattering followed by ozone, water vapor, gas mixture and aerosols are found 0.889, 0.983,0.881,0.987 and 0.698 respectively for 2012 on Kathmandu Valley ((Lat.:27.72°N, Long.: 85.32°E and alt.: 1337 m a.s.l.) (Shrestha et al. 2020). Atmospheric transmittance due to aerosol in Jumla is larger than that in Kathmandu Valley according to study of Shrestha et al.

ACKNOWLEDGEMENT

The authors would like to convey our gratitude to faculty of Central Department of Physics (CDP), Patan Multiple Campus, Institute of science and technology (IoST) for this opportunity as well as DHM and NASA for the data. We sincerely appreciate Nepal Academy of Science and Technology (NAST) for the PhD fellowship. We also like to acknowledge Nepal Physical Society (NPS) and Association of Nepali Physicists in America (ANPA) for educational workshop of Python.
