Abstract

Precise measurements on the conductivity of Sodium nitrate in methanol-water mixed solvent media containing 0.10, 0.20, 0.30 and 0.40 volume fractions of methanol at 308.15, 318.15 and 323.15 K are reported. The concentrations were varied from (0.001 to 0.15) mol.L-1. The results showed a sharp increase in the conductivity with increasing electrolyte concentration. Also, the conductivity of electrolyte increases with increase in temperature whereas the conductivity of electrolyte decreases with increase in the amount of methanol.

Key words: conductivity, sodium nitrate, relative permittivity, mixed solvent media

Introduction

From the concentration dependence of the electrolyte conductivity, different quantities strongly influenced by solvent properties can be derived. Their change with mixed-solvent composition may thus reflect the change in solvent structure and ion-solvent interactions. A binary mixture of water and some organic solvent, with their ratio varying in a wide range, is the most frequently investigated medium (Sokol et al.2006).

Although numerous conductance measurements have been reported in the literature, such studies in methanol - water mixed solvents are relatively rare (Janz et al. 1972). Methanol water mixtures have very special properties, which are different from that of the other alcohol + water mixtures. Ion association has been found to be negligible upto a methanol content of about 80% in the binary solvent. It may be due to the larger dielectric constant of the methanol-water mixtures and the smaller ion size. The transport properties have been investigated for a wide variety of electrolytes in methanol – water mixed solvent media in great detail (Shedlovsky & Kay 1956, Kubota & Masatoki 1976, Zhang et al. 1996, 1997, Kubota & Horimoto 1999; Chatterjee & Das 2006).

Earlier, the transport properties have been investigated (Bhattarai et al. 2006) for a polyelectrolyte in methanol- water mixed solvent media. The experimental data was analyzed by Manning Model and found the lower values than the experimental ones. Later on (Bhattarai, 2008) used the Scaling Theory Approach and obtained good fitting with the experimental data. It is our interest to see the effects of concentration, relative permittivity and temperature on the transport properties of Sodium nitrate in methanol-water mixed solvent media.
Methodology
Methanol (Merck, India) was distilled with phosphorous pentoxide and then redistilled over calcium hydride. The purified solvent had a density of $0.77723 \pm 0.00004 \text{ g/cm}^3$ which was measured by the use of an Ostwald-Sprengel type pycnometer of about 25 cm$^3$ capacity. The solvent was transfused into the pycnometer by using a medical syringe. The pycnometer was then tightly fixed in a thermostat at the experimental temperatures within $0.005 \text{ K}$. After thermal equilibrium was attained, the mass of the pycnometer was measured with an electronic balance, and the density was calculated. Density measurements are precise within $0.00005 \text{ g/cm}^3$, which is satisfactory for our purpose. A co-efficient of viscosity of $0.47424 \pm 0.00005 \text{ mPa.s}$ was determined by the viscometric measurements at 308.15 K a Schultz-Immergut-type viscometer (Schulz Immergut 1952) with a sintered disc fitted to the widest arm to filter the solution/solvent from dust particles, if any and these values are in good agreement with the literature values (Moumouzias et al. 1991). Triply distilled water with a specific conductance less than $10^{-6} \text{ S/cm}$ at 308.15 K was used for the preparation of the mixed solvents. The physical properties of methanol-water mixed solvents used in this study at 308.15, 318.15, and 323.15K are shown in Table 1. The relative permittivity of methanol-water mixtures at the experimental temperatures were obtained by regressing the relative permittivity data as function of solvent composition from the literature (Albright & Gastig 1946).

Table 1. Properties of Methanol-Water Mixtures Containing 0.1, 0.2, 0.3, and 0.4 volume fractions of Methanol at (308.15, 318.15, and 323.15) K.

Sodium nitrate ($\text{NaNO}_3$) employed in these investigations was purchased from Ranbaxy Chemical Company, Inc., India. Conductance measurements were carried out on a Pye-Unicam PW 9509 conductivity meter at a frequency of 2000 Hz using a dip-type cell with a cell constant of 1.15 cm$^{-1}$ and having an uncertainty of 0.01%. The cell was calibrated by the method of Lind and co-workers, 1959 using aqueous potassium chloride solution. The measurements were made in a water bath maintained within $\pm 0.005 \text{ K}$ of the desired temperature. The details of the experimental procedure have been described earlier (Das & Hazra 1992, 1995). Several independent solutions were prepared and runs were performed to ensure the reproducibility of the results. Due correction was made for the specific conductance of the solvent by subtracting the specific conductance of the relevant solvent medium from those of the electrolyte solutions.

In order to avoid moisture pickup, all solutions were prepared in a dehumidified room with utmost care. In all cases, the experiments were performed in three replicates.
Results and Discussion

The experimental specific conductivities of sodium nitrate as a function of the salt concentration ($c_s$) at 308.15, 318.15 and 323.15 K of four different methanol-water mixtures (containing 0.10, 0.20, 0.30 and 0.40 volume fractions of methanol) are depicted in figures 1-3. From these figures, it is evident that the specific conductivities exhibit a sharp increase with increasing concentration within the concentration range investigated here. The increase in the conductance with concentration is due to an increase in the number of ions per unit volume of the solution.

Fig. 1. Specific conductivities of NaN0, as a function of the salt concentration ($c_s$) in 308.15 K: open squares, open circles, closed squares and closed circles represent 0.10, 0.20, 0.30 and 0.40 volume fractions of methanol in the solvent mixture respectively.

Fig. 2. Specific conductivities of NaN0, as a function of the salt concentration ($c_s$) in 318.15 K: open squares, open circles, closed squares and closed circles represent 0.10, 0.20, 0.30 and 0.40 volume fractions of methanol in the solvent mixture respectively.
Obviously, the concentration dependence of the specific conductivity follows the same pattern at all the temperatures and solvent composition investigated. It has been studied earlier that the conductivity value decreases with increase of methanol in the system (Bhattarai et al. 2006). The conductance decreases with increase of alcohol content for the studied methanol-water mixed solvent system. The presence of methanol reduces the dielectric constant of the solvent phase and makes easier for the formation of ion-pairs in the solution phase. In other words, in solvents of low dielectric constants, having small ionizing effect on the electrolytes, the electrostatic forces between oppositely charged ions would be appreciable and conductance value will have small value. However, solvents with high dielectric constants yield more conducting solutions.

The conductivity of an electrolyte depends upon the temperature. With increase in temperature, the conductivity of an electrolyte increases. Here, the conductivity of sodium nitrate increases with increasing temperatures in methanol - water mixed solvent media which was also seen in the system (Bhattarai et al. 2006). The rise in conductance with temperature is due to the decrease in the viscosity of the solution, increase in the speed of the ions and an increase in the degree of ionization.
