ABSTRACT

Introduction: The use of Hawley retainer has crossed a century with same basic principles incorporated one hundred years back accompanying little improvisation in material. The innovation of Hawley retainer was a simple orthodontic appliance yet innovative device of retention of that period of time. The primitive appliance is still continuing over a century; is an achievement in itself. This clearly reflects the intense invention of an inquisitive mind of its creator, Dr. Charles Augustus Hawley.

The present article reviews the chronological events of the life of Dr. Charles Augustus Hawley and his contributions to the profession. Special emphasis has been laid on the evolution, development and clinical aspects of Hawley retainer commemorating its completion of a century.

KEYWORDS: Hawley retainer, Orthodontic Appliance, Retention.

INTRODUCTION

About Dr. Charles Augustus Hawley

Figure 1: Dr. Charles Augustus Hawley (Redrawn from: Wahl N. Orthodontics in 3 millennia)¹

Dr. Charles Augustus Hawley (Figure 1), was born in Avery, Ohio, USA on March 13, 1861 as a son of Noah M and Abigail (Mowry) Hawley.¹² He attended public schools of Columbus, Ohio and the Ohio State University, and graduated from the University of Michigan Dental School in 1893.² After that, he worked at Ann Arbor in the Department of Operative Dentistry, wherein he became the first person to use nitrous oxide as an anesthetic agent for the removal of teeth.³ Later, he joined Edward H. Angle School of Orthodontia and graduated in 1905.³

After graduation, Hawley moved to Washington DC in 1908 and worked there as the first certified orthodontist.⁴ Also, he upgraded his studies on anatomy and physiology of dentition at the National History Museum at Washington.⁵

Coupled with great mechanical dexterity and practical mind, Hawley invented new instruments and methods for carrying out his treatment strategies. According to Hoffman, he was one of the first few orthodontists who recognized an association between unpleasing facial profile and protrusive dentition.³ He has given invaluable contributions to the profession of dentistry and orthodontic specialty; such as: gold annealer, different orthodontic instruments, geometrical charts for predetermining the dental arch and Hawley retainer.¹⁶

Besides, Hawley had published outstanding literature in the field of dentistry and orthodontic specialty in his lifetime,² which are enlisted below in Table 1.

(Source: FTM. In memorium: Hawley CA. Int J Orthod Dent Children. 1929)²

Hawley was actively involved in various scholarly groups of the specialty. In 1908, he became President of the American Society of Orthodontists (presently, American Association of Orthodontists). He also served as the President of District of Columbia Dental Society (1920) and a Fellow of the American College of Dentists. Later, he was President of the New York Society of Orthodontists (1929) and President-elect of the Southern Society of Orthodontists (1929).³

At the age of sixty-eight on 22nd July 1929, he died at Garfield Hospital, Washington DC, following the complications of an operation, leaving behind his wife Evelyn Frank Hawley, a step-son Archibald Donovan Hawley and a daughter Carlotta Augusta Hawley.1-3 His daughter followed his footsteps after his death, became an ABO-certified orthodontist and worked as the first woman secretary of Washington-Baltimore Society of Orthodontics.¹,7,8

From his memoirs, one can find that he was a far-sighted orthodontist and a simple man who loved duck hunting, playing golf and photography.² He has left us with a simple innovative option for retention, the Hawley retainer, that is serving us beyond a century with the same principle and efficiency.

The “Hawley Removable Retainer”

In 1906, Hawley visited the office of Dr. R.D. McBride where he encountered a retaining device (Figure 2), that was useful to retain the corrected position of rotated teeth. It was efficient, but it had some repulsive features that needed alterations. The flat pieces between first molar and second premolar were a site for food lodgments demanding the removal of retainer for few days.⁶ The labial bar was too heavy without supports and the bite planes for holding it mesiodistally were interfering the stability of appliance.⁹

Inspired from the retaining device, Hawley developed a new appliance and started using it. He discussed about the retainer in the meeting of the American Society of Orthodontists on July 1918 at Chicago. After one year, on 1st June 1919, he introduced this appliance (Figure 3 and 4), in his paper as “A removable retainer”, which was made from four components, namely; a flat labial wire from cuspid to cuspid of 0.022 x 0.036, 19-gauge gold wire formed into loops, a bicuspid clasp extending backward from the wire, all of which get support from palatal/lingual plate made from vulcanite.¹ In lower arch, a wire spur extends into occlusal surface between lingual cusps to prevent the plate from downward displacement during mastication.

From his memoirs, one can find that he was a far-sighted orthodontist and a simple man who loved duck hunting, playing golf and photography.² He has left us with a simple innovative option for retention, the Hawley retainer, that is serving us beyond a century with the same principle and efficiency.

In 1922-1923, Hawley presented a paper titled “The
principle and art of retention” in European Orthodontic Society (as cited in the Transactions of the European Orthodontic Society), wherein he perceived mixed comments about Hawley retainer. He also introduced a modified bicuspid clasp (Figure 5), with a spring or elastic adjustment loop above the attachment to the main wire such that it can be raised or lowered. An important remark was from W.S. Davenport, who mentioned that Hawley retainer was a simple device made from the combination of old features of clasp and plate with equal consideration on fundamental principles of retention. Further, he stated that it excluded the shortcomings of retaining device made by Dr. Mcbride and Kingsley Appliance.

With time, Hawley retainer gained popularity among orthodontists and had undergone series of modifications in its components. Ernest Bach (1927), Holt (1928), Hutchinson (1931), Reid (1935), Anderson (1936), McIntosh (1940), Sved (1944) presented modified versions of Hawley retainer to improve clinical failures. After the development of acrylic resins in dentistry, Stevenson improvised Hawley retainer (1941), using acrylic instead of vulcanite, thus making the fabrication simpler and more economic. With the introduction of modified arrowhead clasp (Figure 6 and 7) and its modifications by Phillip Adams (1953); the Adams clasp gained popularity in removable appliances. It ensured retention in clinical situations, which otherwise was difficult with removable appliances. Since then, Adams clasp has been incorporated in Hawley retainer.

Ideal requirements of Hawley retainer
1. Hawley retainer should maintain the corrected functional occlusion, periodontal health and muscular balance, achieved by the orthodontic treatment.
2. It should hold the expansion and form of the arch.
3. The appliance should prevent the rotation of teeth after treatment.
4. The overbite must be established.
5. The retainer should be biocompatible, economical and easy to clean with its components resistant to tarnish and corrosion.

Fabrication
Hawley retainer is fabricated with acrylic resin that covers the palate, a stainless-steel bow contouring the labial aspect of maxillary anterior teeth, with U loops extending from distal surface of canines, and palatally embedding in the acrylic resin. Besides, it incorporates clasps like Adams clasp, circumferential clasp or ball-end clasp, for retention.

The acrylic plate is processed with heat-cure or chemical cure resin. The thickness of plate is made of adequate bulk of 2-3 mm to retain the wire components, with maximal attention to the patient comfort and adaptation into embrasures. Its distal margin terminates distal to first molars, and is thinned to merge with the palatal mucosa.

The wire component includes stainless steel wire of 0.7 mm for Adams clasp, 0.9 mm for circumferential clasp or ball end clasp and 0.7 mm for labial bow. The U loop is fabricated 2-3 mm above the gingival margin of canine and free from gingival contact to avoid injury or pressure effect in gingiva. The labial bow is kept passive and in gentle contacts with labial surface of the teeth.

Modifications
Hawley retainer can be modified according to the clinical requirement for retention. The selection of clasp design is important as clasp crossing the occlusal table can disrupt the corrected tooth relationships. Some modifications are listed in Table 2.
Table 2: Modifications of Hawley retainers

Recent Advances
Hawley with clear outer bow: The aesthetic variant of Hawley retainer was presented by Needham et al in 2015. The appliance was made aesthetic with the incorporation of clear outer bow made of food-grade polyethylene terephthalate of 2.75 mm width, joined at a Coiltight-Joint® to the Adams clasp. It adapts more accurately to the contour of all anterior teeth while posteriorly the wire segment provides retentive component.29

Advantages of Hawley Retainer
1. The armamentarium required for fabrication of Hawley retainer are easily available and sophisticated laboratory set up are not necessary.
2. Being a removable retainer, it can be removed for cleaning, brushing and sometimes, in social occasions.
3. It allows posterior settling and improvement in occlusal contacts.30
4. It can be adjusted according to clinical condition for finished treatments.
5. It is a durable retainer and easily repairable if the components are broken.
6. For a larger period of time, patient compliance is better with Hawley retainer.31

Disadvantages
1. Success of the treatment depends upon patient's compliance.
2. The display of labial wire is unaesthetic, which affects the patient's satisfaction.
3. There is a higher evidence of breakage of this retainer than its loss.32
4. It may not hold the corrected labial segments in upper and lower arch for a larger period of time due to insufficient contact surfaces leading to relapse and incisor crowding.33,34
5. In the first few weeks, patients experience problem in speech articulations.32,35-37

Duration of wear and retention protocol
For the first 2-6 months, Hawley had advised the continuous use of the retainer with removal only during cleaning. After six months, night time wear is recommended for about a year followed by several days or week of left out periods and again usage at nights to ensure that teeth are not changing their positions.6

However, a comprehensive research conducted at the University of Washington, highlighted that retention for life is the only way to ensure satisfactory alignment of the teeth as orthodontic treatment were mostly unstable over a long time.23

Many studies have been performed by different authors regarding the duration of wear,33,38 material biocompatibility,39 monitoring of its wear by the orthodontist,40 hygiene,41,42 durability,32,43 function,30,34,36,44 and patient satisfaction.31 Also, there are comparison studies between Hawley retainers (HRs) and vacuum formed retainers (VFRs) or positioners highlighting its merits and demerits.30,36,39,41-44 Some of the studies are tabulated in Table 3.

DISCUSSION
The retention of corrected occlusion is the most important step after orthodontic treatment. As such, incorporation of basic principles in a retaining device to avoid rotation, tipping, and maintenance of bite depth, is a must. The innovation of Hawley retainer by Dr. Charles Hawley, has been an impeccable addition in this retention phase.

Hawley retainers (HRs) have crossed hundred years of its fabrication and still, these are the most used removable appliance for maxillary retention.23,24 These are available in majority of clinic with least laboratory instruments and costs. Having a lot of modifications, it covers a range of clinical conditions from occlusal settling to anterior deep bite correction. A traditional Hawley retainer allows settling and thus an improvement in posterior occlusal contacts.30

In our clinical context, Hawley retainer is an appropriate
choice when durability is a question. Some authors have inferred that Hawley retainers lasts longer than 15 years.\textsuperscript{23} However, a study by Hichens et al. found that there are greater breakages in HRs group than its loss.\textsuperscript{32}

For most patients, first few weeks of use of this retainer is a demanding process with difficulties in speech articulations and chewing.\textsuperscript{32,35,36} According to a systematic review by Chen J et al., HRs had often caused speech distortion of /s/, /z/, /t/, /d/, /i/, /ӡ/, /θ/, and /∫/ sounds, and the impairment could last up to 3 months.\textsuperscript{37}

There is an esthetic concern for the appliance, due to metallic display of wire, creating an unpleasing experience among patients. Hawley retainer with clear outer bow (aesthetic Clearbow®) can be used in such circumstances.\textsuperscript{28,29} It also provides benefits of being free from bisphenol-A.

Bisphenol-A (BPA) is a synthetic compound enlisted by WHO (2011), as an endocrine disruptive chemical.\textsuperscript{39} A study by Raghavan et al concluded that Vacuum formed retainers (VFRs) showed greatest release of BPA followed by chemically cured HRs and least with HRs processed by heat cure.\textsuperscript{39} Thus, Hawley retainer (either with Clearbow® or heat-cured resin), is a biocompatible option among the retainers.

Being a removable appliance, it can be cleaned thoroughly by the patient. Comparison of these retainers with thermoplastic resins concluded that HRs were more hygienic with less accumulation of plaque in the teeth or retainer.\textsuperscript{41}

When retainer is prescribed for a short period of six months, VFRs have been found to be cost-effective with better compliance but for a duration of more than two years, Hawley retainers were more effective.\textsuperscript{31} Similarly, in developing countries, HRs are considered a cheaper alternative over clear thermoplastic retainers. However, systematic reviews on comparison of these retainers could not draw a high level of evidence to support the benefits of one above the other in terms of cost-effectiveness and patient satisfaction.\textsuperscript{26,45,46}

Relapse was evident over two years in the anterior region of mandibular teeth in majority of retainers.\textsuperscript{44} Though irregularity index decreased in VFRs groups, it could not be concluded that HRs are less effective than VFRs in terms of irregularity of incisors and intercanine and intermolar widths.\textsuperscript{44}

In terms of appliance wear, a survey-based study in US reported that eighty-one per cent of orthodontists prescribed a full-time wear period between 3-9 months for Hawley retainers compared with clear thermoplastic retainers (less than 3 months).\textsuperscript{47} Reitan's concept of rearrangement of gingival and periodontal fibers after 8 months might explain the rationale behind the full-time wear for 3-9 months.\textsuperscript{48} However, there is unavailability of sufficient evidence to favor a particular regimen.\textsuperscript{49} In majority of clinical scenarios, patients are reviewed for over two years after the end of active orthodontic treatment.\textsuperscript{50} Thus, the retention protocol is largely determined by orthodontist's experience, patient's expectations, and clinical circumstances.

There are certain limitations to this study. It is not a systematic research and do not follow a certain protocol. Thus, it lacks the profundity of comprehensive knowledge beyond the topic of interest and may be subjected to bias during selection of literature. However, it provides an overview about the appliance, its associated history and its use through the century.
