INTRODUCTION

A successful establishment of a weed in any ecosystem is attributed to several reasons, such as high growth rate, high reproductive potential, adaptive nature and above all interference by resource depletion and allelopathy (Kohil and Rani, 1994). Allelopathy concerns the effects of one plant on another due to chemicals released by them, or the breakdown products of their metabolites (Willis, 1994). Allelopathy has been suggested as a mechanism for the impressive success of invasive plants by establishing virtual monoculture and may contribute to the ability of particular exotic species to become dominants in invaded plant communities (Hierro, 2003; Kanchan and Jayachandra, 1979). Allelopathy is expected to be an important mechanism in the plant invasion process because the lack of co-evolved tolerance of resistant vegetation to new chemicals produced by the invader could allow these newly arrived species to dominant natural plant communities (Hierro, 2003). In fact, allelopathic interference is one of the important mechanisms for the successful establishment of invasive exotic weeds (Ridenour & Callaway, 2001).

Parthenium hysterophorus, a native of tropical and subtropical America, is the most recent invader in Kathmandu valley. It has already threatened grassland ecosystems of Australia and India to a large extent (Stephen and Sowerby, 1996; Chippendale and Panetta 1994; Goyal and Brahma, 2001). This noxious weed was first reported from Nepal by Hara et al. (1982) but herbarium specimen was collected first in 1967 by Malla from Trishuli (Tiwari et al. 2005). Parthenium hysterophorus appears to be potentially most harmful to native flora, animals and human health. Although it has already invaded grasslands of most of the urban cities (e.g. Kathmandu, Pokhara, Narayangarh, etc) and near highways in tropical to subtropical region no effort has been made to control Parthenium hysterophorus, neither there is any study in Nepal to examine the effect of its invasion to native ecosystem. To explore allelopathic potential of Parthenium hysterophorus we examined effect of aqueous extract of leaves of this plant on seed germination and seedling growth of some cultivated and wild herbaceous species growing naturally together with Parthenium hysterophorus.

MATERIALS AND METHODS

Species Characters

Parthenium hysterophorus L. (Family: Asteraceae; common names: Bitter weed, false ragweed, fever few, Parthenium weed, Ragweed, white top, etc; vernacular names: Kanike ghans, Bethu ghans, or Padke phul) is an annual, erect and profusely branched herb. Height varies between 50-150 cm.
stem highly branched; leaf simple with profusely dissected leaflets; flower heads occur on a corymb, phyllaries 10 in 2 series, ovate, dull white, 3-4 mm in diameter; disc floret: numerous, dull white; stamen - 4, anther- exerted; ovary sterile; ray floret: found just opposite to inner phyllaries, only 5 ray florets per flower head, corolla obsolete, stamen-absent, stigma-parted, style short, ovary oval, dorsiventrally flattened. Fruit cypsela, each flower head bearing 5 cypsela, flat and triangular in shape with thin, white, spoon shaped appendages (Maharjan, 2006). A typical mature plant can produce from 15000 to 25000 seeds (Haseler, 1976; Joshi, 1991).

Collection of Plant Materials

Fresh leaves of Parthenium hysterophorus in its vegetative stage were collected from roadside fallow land of Kirtipur (27º 40.948’ N, 85º 18.120’ E, alt. 1320 m asl) and air dried in shade for a week. The dried leaves were stored in plastic bags for one month at room temperature (average during day: 25ºC) before used for experiments.

Experiments

From preliminary screening it was found that leaf extract had the strongest allelopathic effect on seed germination; thus we selected leaves for detail experiments. Ten gram of air dried leaves of Parthenium hysterophorus was ground, mixed with 100 ml distilled water and left for 24 h in dark at the room temperature (average during day: 25ºC) for extraction. Aqueous extract was obtained as filtrate of the mixture and final volume was adjusted to 100 ml; this gave 10% aqueous extract. The extract was considered as stock solution and a series of solution with different strengths (2, 4, 6 and 8%) were prepared by dilution. Ten uniform and surface sterilized seeds (2% sodium hypochlorite for 15 min) of rice (Oryza sativa L. local var. khumal 4) were kept for germination in sterilized petri-dishes lined double with blotting paper and moistened with 10 mL of different concentrations of aqueous extracts (2 to 10%). Each treatment had three replicas (total number of test seeds: 10 x 3 = 30). One treatment was run as control with distilled water only. The petri-dishes were maintained under laboratory conditions (room temperature 25ºC at mid day, and diffused light during day) for one week. Equal volume of distilled water was added in the dishes when moisture content of the blotting paper declined. After one week, number of germinated seeds were counted and, the root and shoot length were measured. All root and shoot from each petridish were cut separately and oven dried at 70ºC for 48 h to get dry biomass of root and shoot; total

seedling biomass of seedling was calculated as the sum of biomass of root and shoot.

Same procedure was followed to evaluate allelopathic effects of *P. hysterophorus* on seed germination and seedling growth of other two cereal crops: maize (*Zea mays* L. local var. Rampur Composite) and wheat (*Triticum aestivum* L. local var. Godavari); three crucifers: radish (*Raphanus sativus* L. local var. Mino early), mustard (*Brassica campestris* L. local var. Khumal rato pat), and cauliflower (*Brassica oleracea* L. var. *botrytis* L. local var. *Jyapu*); and two wild Asteraceae *Artemisia dubia* Wall ex. Besser and *Ageratina adenophora* (Spreng) King and HE Robins.

**Statistical Analysis**

Significance of the difference in root and shoot length of seedlings under different treatments were tested and compared using Analysis of Variance (ANOVA) and Homogeneity test. Regression analysis between treatments vs. root and shoot length of seedlings among cereals, crucifers and wild Asteraceae were done by compiling all data of cereals, crucifers and wild Asteraceae. Change in germination percentage with concentration of aqueous extract was evaluated using regression analysis for the combined data of all test species. All statistical analyses were done using Statistical Package for Social Sciences (SPSS version 11.5, 2002).

**RESULTS**

**Germination**

Except in *Zea mays*, there was complete failure of seed germination of test species in 10% aqueous extract. Even in 6% and 8% there were no germination of *Triticum aestivum* and *Ageratina adenophora*. The inhibition of germination was found strong in the crucifer species (*Raphanus sativus, Brassica campestris* and *Brassica oleracea*); there was no germination at >2% concentration (Fig. 1B). At 2% concentration, germination of *Brassica oleracea* was found to be reduced more as compared to control (67.86%) followed by *Triticum aestivum* and *Brassica campestris* (50%) (Fig. 1). At 4% concentration, among germinating species (*Oryza sativa, Triticum aestivum, Zea mays, Ageratina adenophora* and *Artemisia dubia*), the *Triticum aestivum* showed maximum reduction in germination (92.3%) over control. The regression analysis between germination percentage and concentration of extract showed that 65% of variation in germination of the test species could be explained by concentration of leaf extracts ($R^2 = 0.65$, Fig. 2).

**Seedling Growth**

ANOVA showed significant difference ($p<0.001$) between treatments in root and shoot length of all test seedlings (Table 1). Among the cereal species there was highest reduction in the root and shoot length of *Triticum aestivum* (Table 2). The homogeneity test showed that root length of *Oryza sativa* at 2 – 6% was significantly different from that of control. The root length of *Triticum aestivum* at 4% and 2% were significantly different from that of control. Whereas in *Zea mays*, root length at 4 – 10% was different from that of control. Among crucifer species, the root length of *Brassica campestris* was highly reduced (92.79%) at 2% concentration as compared to control. Among the wild Asteraceae the root length of *Ageratina adenophora* was reduced more (70.59%) at 4% as compared to control. The root length of *Ageratina adenophora* at 2% and 4% and that of *Artemisia dubia* at 2-8% were significantly different from that of control in both the cases (Table 2).

The shoot length at 4-6% were significantly different from that of control in *Oryza sativa* (Table 2). The root length of *Triticum aestivum* at 2% and 4% were significantly different from that of control whereas in *Zea mays* it was different from control only at 6-10%. Among crucifer species there was highest reduction in shoot length of *Brassica oleracea* (80.2%) at 2% concentration (Table 2). Among Asteraceae the shoot length of *Ageratina adenophora* declined more
(60.78%) at 4% concentration as compared to control. The shoot length of *Ageratina adenophora* at 2% and that of *Artemisia dubia* at 6% and 8% were significantly different from that of control in both the cases (Table 3).

Regression analysis between treatments vs. root and shoot length among cereals, crucifers and wild Asteraceae showed that the root length and shoot length of all species declined with increasing concentration of the extract (p<0.001) (Fig. 3) but at higher concentration reduction was high for root length in the cereal, and for shoot length in crucifer and wild Asteraceae (Fig. 3). In these cases high reduction was indicated by higher slope of regression line.

Shoot and root biomass of seedlings of *Oryza sativa*, *Artemisia dubia* and *Ageratina adenophora* couldn't be measured because the mass was beyond the limit of our balance (0.001g). Among the remaining species shoot and root biomass of *Zea mays* seedlings were the highest (Fig. 4).

**DISCUSSION**

From preliminary screening it was found that leaf extract had the strongest allelopathic effect on seed germination. Tefera (2002) also found that the inhibitory allelopathic impact of leaf extract was more powerful than of other vegetative parts.

Phytochemical analysis had already reported high accumulation of growth inhibitors in leaves of *Parthenium hysterophorus* (Kanchan 1975).

The study demonstrated that leaf aqueous extracts of *Parthenium hysterophorus* exhibited significant inhibitory effects on seed germination and seedling growth of all test species (three cereal crops, three crucifer vegetables, and two Asteraceae species (Figs. 1, 2, Table 2). Earlier works have also reported that foliar leachates of *Parthenium hysterophorus* reduced root and shoot elongation of *Oryza sativa* and wheat (Singh and Sangeeta 1991), maize and soyabeans (Bhatt et al. 1994) as well as some common Australian pasture grasses (Adkins and Sowerby 1996). This indicates the availability of the inhibitory chemicals in higher concentration in leaves than in stem and roots (Kanchan and Jayachandra 1980). The regression analysis between germination percentage and extract concentration showed that the germination of the test species were significantly (p<0.001) reduced with the increase in the concentration (R² = 0.65, Fig. 2). Among the treatments, 8% and 10% aqueous extracts had the strongest inhibitory effect on germination (Fig. 1). Terera (2002) also reported that 10% leaf aqueous extract of *Parthenium hysterophorus* resulted in complete failure of seed germination in *Eragostis tef*. Singh et al. (2005b)

**Table 2:** Effect of aqueous extract of *Parthenium hysterophorus* on root and shoot length of different plant species measured after one week. Different letters in superscript of the values in vertical rows indicate that the values are significantly different (á = 0.05).
also found a strong positive correlation between extract concentration of residues of *Parthenium hysterophorus* and reduction in seedling length of *Brassica* species. The 10% leaf aqueous extract completely inhibited seed germination of *Oryza sativa*, *Triticum aestivum*, *Zea mays*, *Ageratina adenophora* and *Artemisia dubia*. *Raphanus sativus*, *Brassica campestris* and *Brassica oleracea*. This could occur only when some allelochemicals present in the leaf extract prevented growth of embryo, or caused the death. The extract of *Parthenium hysterophorus* induced a variety of chromosomal aberrations in dividing cells, which increased significantly with increasing concentrations and durations of exposure (Rajendiran 2005). At 4% concentration, among germinating species (*Oryza sativa*, *Triticum aestivum*, *Zea mays*, *Ageratina adenophora* and *Artemisia dubia*), the *Triticum aestivum* showed maximum reduction in germination (92.3%) over control. A reduction in seed germination of wheat by 80-90% due to soaking of its seeds in stem aqueous extract of *Parthenium hysterophorus* for 20 and 40 h has been reported by Rajan (1973). Srivastava et al. (1985) revealed that aqueous extracts of leaves and inflorescences inhibited the germination and seedling growth of barley, wheat and peas. In present study there were strong inhibition in seed germination of the crucifer species (*Raphanus sativus*, *Brassica campestris* and *Brassica oleracea*) even in 2% concentration and complete inhibition above this (Fig. 1B). The seeds of these crucifers appeared in: Figure 3: Relationship between concentration of leaf aqueous extract of *Parthenium hysterophorus* and root (a) and shoot (b) length of (A) cereal species, (B) crucifer species and (C) wild Asteraceae.
to be the most sensitive among the test species to inhibitory effect of leaf aqueous extract of *Parthenium hysterophorus*. Since crucifers are important vegetables and cash crops of Kathmandu valley, invasion by *Parthenium hysterophorus* into farmland may have adverse effect on local agroeconomy.

From the homogeneity test it was found that the shoot length of all the test species (except *Ageratina adenophora*) at 2% concentration was not significantly different from that of control; whereas at the same concentration (2%) root length (except in *Zea mays*) was significantly different from the control (Table 2). It indicated that root elongation was affected more than of the shoot. Similar effect of leaf aqueous extract of *Parthenium hysterophorus* was reported by Tefera (2002) on *Eragrostis tef* and Rajan (1973) on wheat. The strong inhibitory effects that *Parthenium hysterophorus* had on root elongation might be due to direct contact of root with the extract and subsequently with inhibitory chemicals as described in early works with various crops and weeds (Bhowmik and Doll 1984, Quasem 1995). At higher concentration reduction in length was higher for root than shoot in cereals (higher slope of regression line for RL, Fig. 3A); for crucifers and wild Asteraceae reduction in shoot length was higher than reduction in root length at higher concentrations (Fig. 3B, C) Thus sensitivity to allelochemicals and extent of inhibition varied with species and organs of the test species.

The inhibitory effect of *Parthenium hysterophorus* on seed germination and seedling growth of different plant species is due to presence of growth inhibitors (allelochemicals) in the extracts. Rajan (1973) and Kanchan (1975) were the first to report the presence of plant growth inhibitors in *Parthenium hysterophorus*. This plant releases a number of water soluble allelochemicals such as phenolic acid and sesquiterpene lactones, particularly parthenin (Kanchan 1975, Swaminathan *et al.*, 1990, Stephen and Soverby 1996). Phenolics found in leaves also have inhibitory effects on growth of nitrogen fixing and nitrifying bacteria (Kanchan and Jayachandra 1981). According to Rice (1984) phenolics are the most common and widely distributed water soluble allelochemicals. The escape of these chemicals into the environment occurs through various mechanisms such as leachation, volatilization and microbial decay of dead and fallen parts, as well as root exudation (Rice 1984). These chemicals were reported to have had allelopathic potential on various agronomic crops and weeds (Stephen and Soverby, 1996; Mersie and Singh, 1987) and vegetable crops (Mersie and Singh, 1988). Patil and Hedge (1988) isolated parthenin in pure form from the leaves of *Parthenium hysterophorus* and demonstrated that this compound significantly decreased germination of wheat seeds and adversely affected seedling growth.

According to Kanchan and Jayachandra (1979) and Pandey (1994), *Parthenium hysterophorus* is one of the best known plant invaders in the world linking allelopathy to exotic invasion. The unique allelopathic effects of some exotic species on naïve, ‘inexperienced’ communities (Callaway and Aschehoug, 2000) also contribute to invasive success. Allelopathy is expected to be an important mechanism in the plant invasion process. Lack of co-evolved tolerance of resident vegetation to new chemicals produced by the invader could allow these newly arrived species to dominate natural plant communities (Hierro and Callaway 2003). *Parthenium hysterophorus*, because of its invasive capacity and allelopathic properties, has the potential to disrupt natural ecosystems (Evans 1997). It has been reported as causing a total habitat change in native Australian grasslands, open woodlands, riverbanks and floodplains (McFadyen 1992, Chippendale and Panetta 1994).

According to Tiwari *et al.* (2005) *Parthenium hysterophorus* has not been used for any purpose in Nepal. Therefore this plant may become a high risk posed invasive species in near future. Present results showed that concentrated aqueous extract of leaves of *Parthenium hysterophorus* inhibited seed germination and seedling growth of other weeds such as *Ageratina adenophora* and *Artemisia dubia*, former being another invasive plant of the region. This result is also supported by similar previous reports of Batish *et al.* (1997, 2002). They reported germination inhibition of *Amaranthus viridis*, *Chenopodium murale* and *Ageratum conyzoides* by *Parthenium hysterophorus*. Thus, this plant could be exploited as a source of natural herbicides by maximizing its use for future weed management programmes.

**CONCLUSIONS**

The crucifer species (*Raphanus sativus, Brassica campestris* and *Brassica oleracea*) were more sensitive to inhibitory...
effects of leaf aqueous extract of Parthenium hysterophorus. Germination was completely inhibited at >2% concentration in crucifer species. Except in maize, complete failure in seed germination of all test species were recorded at 10% extract. There was no seed germination of Triticum aestivum and Ageratina adenophora even at 6% and 8%. The extract had strong inhibitory effect to root elongation of seedlings in cereals and to shoot elongation in crucifers and wild Asteraceae. Thus, sensitivity to allelochemicals and extent of inhibition varied with species and organs of the test species. Allelopathic effect of Parthenium hysterophorus may be an important mechanism involved in invasive success of this plant. Allelochemicals of this plant can be exploited as a source of natural weedicide to control other invasive species.

ACKNOWLEDGEMENTS
The help of Mrs. Sajag Adhikari during laboratory work is thankfully acknowledged.
