Abstract
Congenital thyroid anomalies are rare. Developmental anomalies may be in the form of unilateral or bilateral hypoplasia or agenesis of one or both lobes of thyroid with or without isthmic agenesis. Most of the times when they are detected incidentally already have associated thyroidic diseases. We report a 36-year-old female presented with right thyroid hemiagenesis and isthmic agenesis associated with thyroiditis in left lobe of thyroid.

Key Words: Agenesis, congenital, ultrasound, thyroid

Introduction
Hemiagenesis of thyroid lobe is a rare embryological disorder which results from failure of one lobe of thyroid development. Most of the time they are detected either by clinical symptoms with associated thyroidic diseases or by incidental findings on imaging or by obvious anatomical variations. Embryological development of the thyroid gland starts in the primitive pharynx in form of an invagination of the endoderm which grows ventrally while remaining attached to the pharyngeal floor. This rudiment will then migrate to its actual anatomical position that is anterior to the pharynx and after that it begins to grow laterally to create the bilobed thyroid gland¹.

Congenital anomalies of thyroid may be either by abnormal descent of the gland or by incomplete genesis of a lobe; however the exact etiopathologies of the hemiagenesis is still unclear². Most of the cases are sporadic, a few may be familial and there may be a genetic predisposition. These patients may depict normal thyroid lobe with euthyroidism³, and both hypothyroidism⁴ and hyperthyroidism⁵,⁶. Hemiagenesis of thyroid was first reported in the year of 1852 by Handsfield Jones⁷. Left sided hemiagenesis is quite common than the right with a ratio of 4:1 and female predominance with a ratio of 3:1⁸. Very few literatures have been published in scientific journal about this rare developmental anomaly from our country. Herein we report an uncommon case of 36-year-old female with right sided hemiagenesis of thyroid with isthmic agenesis associated with Thyroiditis.

Case Report
A 36-year-old woman gravid 3, para 2 came to our centre for regular body check up. She had a complain of throat pain with whole body muscular pain. She was a regular patient for a renowned hospital in Kathmandu. She had a medication history of taking 75mcg thyronorm per day. This time she came to our centre as convenient to her. Her body weight was 63kg, height, 150cm, Body Mass Index was 28, and Blood pressure as recorded
was 120/90mmHg. She had undergone cesarean section for her second child 6 years ago. On physical examination the thyroid gland was nonpalpable on the left side. Serum thyroid hormones were mildly-moderately low; serum free T3 was 1.9 pg/ml (normal range: 2.3-4.2 pg/ml) and free T4 was 0.65 ng/ml (normal range: 0.89-1.8 ng/ml) and TSH 26.00. (3rd Generation Ultrasensitive TSH; Normal range 0.35-5.29). Antithyroglobulin and anti-thyroperoxidase autoantibodies were negative.

Ultrasound was performed by Esaote My Lab 40 machine equipped with 12.5 MHz linear transducer. Grey Scale US revealed no thyroid tissue on the right side (white arrow heads in panel C) with partial or absence of isthmus (Figure 1, panel A). Left lobe of thyroid revealed slightly heterogenous and coarse parenchymal echotexture with no increased in parenchymal vascularity in color Doppler imaging (Figure 1; Panel B and C). With the diagnosis of hemiagenesis of right lobe of thyroid and agenesis of isthmus with features of thyroiditis in left lobe ultrasound report was dispatched. She was managed by medicine with 100 mcg dose of thyronum follow up after three months revealed normal level TSH and no abnormal lymphnodes with no complaint.
Discussion
Thyroid hemiagenesis is a rare congenital anomaly with absence of a lobe or a lobe along with the isthmus. Embryologically it develops in the midline from the pharyngeal floor at the foramen caecum. The true prevalence of thyroid hemiagenesis is yet unknown, however few study revealed that estimated prevalence rate to be ranged between 0.05 and 0.2% with the female predominance with the commonest site being the left lobe as in our case. A study conducted by Ruchala et al in 2010 concluded that hemiagenesis of thyroid were more likely to develop thyroid pathology. The most frequent associated thyroid disorders according to Ruchala et al. were thyroid nodules and autoimmune thyroid diseases. Simple goiter and nonautoimmune subclinical hypothyroidism were less often observed. In our case features of thyroiditis were reported on grey scale and color doppler songrams. Ultrasound as being the firstline modality to image the thyroid gland; is feasible, convenient and cheaper than MRI or scinitgraphy. As in our case agenesis of right lobe of thyroid and isthmus was established by ultrasound. Thyroid hemiagenesis though is a rare abnormality, routine exams or screening on ultrasound would be a great helpful for the endocrinologist and other physician to rule out associated thyroid nodules or other thyroid diseases.
