Abstract

Background: Diabetes Mellitus (DM) is a major public health problem worldwide and Nepal is not an exception. Complications of DM are in rise which results in major disabilities and poor quality of life. But evidences show that adoption of self-care practices can prevent those complications leading a healthy and quality life. Self-care practice is closely related to self-efficacy. Thus, present study aimed to assess perceived self-efficacy and self-care practices and to examine relationship between perceived self-efficacy and self-care practice of patients with Diabetes. Methods: This analytical cross-sectional study conducted in Patan Hospital among 100 patients was reviewed and approved by Institutional Review Committee. Samples were selected purposively and data was collected by face to face interview technique. Diabetes Self-Efficacy Scale and self-care practice questionnaire was used to measure self-efficacy and self-care practice, respectively. Results: Fifty nine percent and 81% of participants had moderate level of perceived self-efficacy and good self-care practice, respectively. There was significant moderate positive (r=0.62, p<0.001) correlation between perceived self-efficacy and self-care practice even after controlling the variables (e.g. age, gender and participation in educational program regarding self-care). Conclusion: The self-efficacy of participants was moderate and self-care practice was good. However, self-care practice was very low on foot care and exercise. The significant positive relationship between perceived self-efficacy and self-care practice highlights the need for conducting educational activities for patients with DM to increase self-efficacy thereby increasing self-care practice.

Keywords: Diabetic patients, Perceived self-efficacy, Self-care practices.

Background

Diabetes Mellitus (DM) is a major public health problem worldwide.1 Globally, the number of adults living with DM was 463 million in 2019, of which, 79% were living in low and middle income countries.2 The global prevalence of DM is estimated to increase from 8.8% in 2015 to 10% in 2030.3 On the other hand, the burden of diabetes has been increased at a greater rate in low and middle-income countries than in high income countries, both in terms of prevalence and number of adults with DM.4 Nepal is not an exception where, it has been estimated that the prevalence of DM will increase from 4.5% in 2013 to 5.4% in 2035.4 There were 696,900 cases of DM in Nepal in 2019 which is 4% of the total adult population (17,570,100).2 The systematic review and meta-analysis from 2000 to 2014 showed that the prevalence of type 2 DM in Nepal was 8.4%, of which 8.1% in urban population and 1.0% in rural population.8 Similarly, the global DM attributed mortality has been increased by 34.7% which is higher to Type 2 DM.7 In Nepal, the mortality related to DM has increased from 2% to 4% from 2010 to 2016.8,9 The common diabetes related complications found in Nepalese people are retinopathy (37.3%), diabetic foot (30.4%), peripheral neuropathy (7.8%),

cardiovascular diseases (2.9%), and nephropathy (2%)\textsuperscript{9}, leading to major disabilities that require majority of resources to be used to treat diabetes complications.\textsuperscript{11,12} However, people with diabetes can live long and healthy lives if their diabetes is early detected and well-managed.\textsuperscript{1} In order to reduce this burden, there are various modifiable risk factors which can be modified through behavioral changes and patients with diabetes need to adopt self-care behaviors to improve both the quality of life and life expectancy.\textsuperscript{1,11} On the basis of sustainable development goal 3, Nepal has targeted to reduce death from diabetes out of all deaths from 1.7% to 0.5% from 2014 to 2030\textsuperscript{13} which can be achieved by preventing the complications of DM.

Patient’s perceived self-efficacy has been shown to have positive correlation with self-care practice.\textsuperscript{14} It refers to the level of self-confidence of a person in performing particular goal-directed behavior successfully.\textsuperscript{15} In context of DM, these goal-directed behaviors, refer to the self-care practice that patient with DM needs to follow on a daily basis including dietary control, physical activity, adherence to medication, foot care and monitoring blood glucose level\textsuperscript{16} which helps to reduce the complications or delay the complications thereby increase the quality of life of patients with DM. A self-efficacy education program on foot self-care behavior of patients with diabetes showed that after the intervention, self-efficacy increased significantly from baseline (median = 30.00 to 44.00, \(Z = -4.76, \ p<0.001\)) and also self-care behavior levels significantly increased from baseline (median = 45.00 to 69.00, \(Z = -4.86, \ p<0.001\)).\textsuperscript{17} Another study showed that higher the self-efficacy score was significantly associated with active self-management behaviors (odds ratio = 1.06; 95% CI: 1.04 – 1.08).\textsuperscript{18} Thus, it can be concluded that self-efficacy and self-care behavior of patient with diabetes might have a causal relationship.

The level of self-care practices of patients with DM vary among different countries and also among different regions within the country as well. In Nepal, there are studies carried out to assess the self-care practice of patients with DM. For instance, it was found that 61.8% of the patients had good practice in a study conducted in Eastern region (Dharan)\textsuperscript{19} whereas, it was 47.3% in a study conducted in Western region (Pokhara).\textsuperscript{20} Similarly, in regard of self-efficacy, it was found moderate and its relationship to self-care practice was positive (\(r=0.47, \ p<0.001\)).\textsuperscript{14} In conclusion, self-care practices of patients with DM are different within country and self-efficacy of Nepalese patients with DM has not been explored much. Self-care practices are the activities which are economical and can be carried out by patients themselves to prevent the complications of DM.

The differences found in the results of various studies carried out within the country might have been due to different level of perceived self-efficacy of the patients in various places as it has shown strong correlation with the self-care practices. There are very few studies that explored the perceived self-efficacy and its relationship with self-care practices of the patients with DM in Nepal, thus it is very important to assess the perceived self-efficacy and self-care practices among the patients with DM and their relationship so that interventions can be applied to build up the confidence of the patients in carrying out the self-care activities thereby reducing the complications of DM. Hence, the present research aimed to determine the level of perceived self-efficacy, self-care practices among patients with diabetes and their relationship. This study was guided by Nola J. Pender’s health promotion model (1996)\textsuperscript{15} where individual characteristics and experiences may directly affect the self-efficacy and self-care practices of patients and the self-care practices may differ with the level of perceived self-efficacy of the patients.

**Methods**

A cross-sectional analytical study was carried out at Medical Outpatient Department (OPD) of Patan Hospital, Kathmandu, Nepal between September and November 2019.
All patients with Type 2 Diabetes Mellitus (T2DM) who were receiving care at Patan Hospital were the study population. We purposively selected 100 samples from patients with T2DM aged ≥ 18 years old who have been diagnosed with T2DM for at least 1 year duration and willing to participate in the study. Patients with Type 1 DM, gestational diabetes were excluded from the study and, also patients with Type 2 DM who were not able to perform activities by themselves and did not understand Nepali language were excluded from the study.

The study was conducted after the ethical approval from Institutional Review Committee, Patan Academy of Health Sciences (Ref: PNC 1906141255). Participants were explained about the research detail, its significance, the benefit and harm in Nepali language before obtaining the consent, their queries were answered. A statement indicating that the participants has understood all the information in the consent form and is willing to participate voluntarily was obtained. Participants were able to withdraw from the study at any time without giving any reason during the study period. The confidentiality of participants was assured and code number was used in each interview schedule and name of the participants was not mentioned anywhere.

Data were collected using Diabetes Self-Efficacy Scale (DSES) for perceived self-efficacy and self-developed self-care practice related rating scale for self-care practices. Initially self-care practice questionnaire was developed in English. Both tools were forward and backward translated utilizing the guideline. The content validity was done (CVI = 0.96). The Cronbach’s alpha of the original DSES tool was 0.85.

Self-efficacy: Diabetes Self-Efficacy Scale (DSES) was used to measure perceived self-efficacy. It is an 8 item 10-point rating scale developed by Self-Management Resource Center. It was modified into a 5-point rating scale as of previous literature considering the cultural context of Nepal where 1 is not at all confident and 5 is totally confident. The Cronbach’s alpha of the modified tool in the previous study was 0.78. The total score ranges from 8 to 40. Mean of 8 items is the score for the scale. Higher score indicates higher self-efficacy. Level of perceived self-efficacy was categorized into three levels: High (≥4), Moderate (3 – 3.9) and Low (<3).

Self-care practice: Self-developed questionnaire for self-care practice was used to measure self-care practice. It is a 5-point rating scale in which 5 indicates always, 4 indicates often, 3 indicates sometimes, 2 indicates rarely and 1 indicates never. It consisted of 24 items with 5 domains namely; Diet, Medication, Exercise, Foot care and Blood Glucose Monitoring. Total score ranges from 24 to 120. Mean of the total scores of 24 items was the overall score for the scale. The level of self-care practices was categorized into two levels based on interquartile range where good self-care practice is score >3 and Poor self-care practice is score ≤3. Informed written consent in Nepali language was obtained from each participant. Data was collected by face to face interview using semi-structured interview schedule in Nepali language at OPD setting before doctor check-up. It took approximately 35 minutes for each participant. Each day, 2 to 6 participants were interviewed according to the availability of the participants for a month. Statistical Package for Social Sciences version 16 was used for analysis of data. Descriptive statistics and Pearson’s Correlation Coefficient was used for analysis. Data were checked for normal distribution using both graphical presentation (Q-Q plot and histogram) and statistics (Kurtosis, Skewness and Saphiro-Wilk test). It was found that the data were normally distributed. Level of significance was set at 0.05 level.

Results
The median age of participants was 55 years (IQR=15) and most of the participants were female middle aged and most of them had not participated in any self-care practice of DM related educational program (Table 1).

**Self-efficacy and self-care practice**

Most of the participants (94%) had moderate to high level of self-efficacy. However, based on the mean score the self-efficacy was moderate (Table 2). Regarding self-care practice, 81% of participants had good self-care practice and based on the mean score the average self-care practice was good (Table 2).

**Correlation between self-efficacy and self-care practice**

There was significant positive moderate correlation (r = 0.62, p < 0.001) between perceived self-efficacy and self-care practice of participants even after controlling age, gender and education regarding self-care practice (Table 4).
Table 4. Correlation between Perceived Self-efficacy and Self-care Practices of Patients with Diabetes

| Perceived self-efficacy | 1 | | | | | | | |
| Self-care practice | 0.62* | 1 | |

*. Correlation is significant at the 0.01 level (2-tailed).

Discussion
The average perceived self-efficacy of the participants was moderate. This finding is similar to the study conducted in Indonesia.25 However, in a study conducted in Malaysia average perceived self-efficacy among patients with diabetes was high.16 The individual characteristics and experiences of participants may directly affect their perceived self-efficacy.15 In this study, personal factors (age, gender, and attending educational program related to diabetic self-care practices) may have affected the perceived self-efficacy of participants but its effect has not been studied in this study. These factors may have direct effect on the self-efficacy of participants as suggested by the Health Promotion Model which implies, younger patients may have higher self-efficacy than elder patients and patients who have attended educational programs may have better self-efficacy. Some of the factors as explored by previous studies that affect perceived self-efficacy are educational level, diabetes distress, and depression.27 Self-efficacy is found to be higher among patients having higher educational level and lower among depressed and distressed patients.27 Regarding self-care practice, average self-care practice of participants was good. This finding is similar to the study conducted in Dharan, Nepal19 and also a study conducted in Ethiopia.28 On the other hand, in a study conducted in India29 and in Pokhara, Nepal20, the average self-care practice of participants was poor. The self-care practices of the patients with diabetes at different places of Nepal are found to be different. It may be due to various factors such as characteristics of patients or their level of self-efficacy as suggested by the Health Promotion Model of Pender. The clients who never attended diabetes health education program had 4 times more chances of having poor self-care practice (AOR = 4.09, 95% CI 1.89,8.84, p <0.001) than who had attended the program.28 On the other hand, it was found that males, who had higher education, and those with a higher per-capita income were found to have better self-care practices in most aspects like physical exercise, regular blood sugar testing and follow up visits.29 However, in this study, when analyzing the score the average score falls on the lower boarder (i.e. 3.35) indicating that there is still need to increase the level of self-care practice of patients with DM. It is important to conduct similar studies at various parts of the country to generalize the actual scenario of the self-care practices of patients as a whole. In this study, about 20% of participants had poor self-care practice, who are at higher risk of developing diabetes related complications which will affect their quality of life and also increase the health care expenditure.

When analyzing the domain of the self-care practice, the highest self-care practices carried out was on blood glucose monitoring followed by medication whereas, least performed self-care practice was on foot care. This finding is similar to the study conducted in India.30 However, in the
study conducted in Malaysia\textsuperscript{16}, least performed self-care was blood glucose testing. The findings of this study suggest that it is necessary to focus on the least performed self-care practice of participants which is on foot care and exercise as it has been found that about 30\% of diabetic related complications in Nepali patients with DM are diabetic foot.\textsuperscript{10} There are various factors which affect the self-care practices of patients with DM such as education level, employment status, and duration of illness, perceived social support, and perceived self-efficacy\textsuperscript{19} as demonstrated by various studies suggesting exploring the factors affecting the self-efficacy of patients with DM in different settings.

In this study, there was significant moderate positive correlation between perceived self-efficacy and self-care practice of participants (r = 0.62, p-value < 0.001) even after controlling the variables such as age, gender and attending educational program. This finding is similar to the study conducted in Malaysia (r = 0.538, p < 0.001)\textsuperscript{19} and Iran (r = 0.39, p < 0.001).\textsuperscript{31} This positive relationship between self-efficacy and self-care practice implies that one of the measures for improving self-care practices of the patients with DM is to uplift their self-confidence in performing those activities. Improving their self-care practices will help to prevent the complications of diabetes.

Limitation of the study
The findings of the study may not be generalized to all the patients of DM in Nepal as it was conducted in only one setting at tertiary hospital. Probability sampling technique covering the larger population may help to generalize the study findings.

Conclusion
The average self-efficacy of patients with DM was moderate and self-care practice was good. However, the score of good self-care practice was on lower side indicating that there is still a need to increase the level of self-care practice of patients with DM. The higher self-efficacy was associated with good self-care practice suggesting that there is a need to increase the level of self-efficacy of patients with DM from moderate to high self-efficacy.
